This paper is dedicated to Alexander Mielke on the occasion of his 60th birthday.

ABSTRACT. In this paper we present a stochastic homogenization result for a class of Hilbert space evolutionary gradient systems driven by a quadratic dissipation potential and a Λ -convex energy functional featuring random and rapidly oscillating coefficients. Specific examples included in the result are Allen-Cahn type equations and evolutionary equations driven by the p -Laplace operator with $p \in (1, \infty)$. The homogenization procedure we apply is based on a stochastic two-scale convergence approach. In particular, we define a stochastic unfolding operator which can be considered as a random counterpart of the well-established notion of periodic unfolding. The stochastic unfolding procedure grants a very convenient method for homogenization problems defined in terms of (Λ -)convex functionals.

1. Introduction. Homogenization theory deals with the derivation of effective, macroscopic models for problems that involve two or more length (or time) scales. In stochastic homogenization the considered models are described in terms of coefficient fields that are randomly varying on a small scale, say $0 < \varepsilon \ll 1$. A typical situation involves stationary random coefficient fields of the form $\mathbb{R}^d \ni x \mapsto a(\omega, \frac{x}{\varepsilon}) = a_0(\tau_{\frac{x}{\varepsilon}}\omega)$ where $\omega \in \Omega$ stands for a “random configuration” and a_0 is defined on a probability space (Ω, \mathcal{F}, P) that is equipped with a measure preserving action $\tau_x : \Omega \rightarrow \Omega$, see Section 2 for the precise description of random coefficients.

In this paper we consider stochastic homogenization of gradient flows defined in terms of two integral functionals with random and rapidly-oscillating integrands—a quadratic *dissipation* functional $\mathcal{R}_\varepsilon : Y \rightarrow \mathbb{R}$ and a Λ -convex *energy* functional $\mathcal{E}_\varepsilon : Y \rightarrow \mathbb{R} \cup \{\infty\}$. In particular, these functionals are defined on a state space

$Y = L^2(\Omega \times Q)$ (the dual space is denoted by Y^*), where $Q \subset \mathbb{R}^d$ is open and bounded, and they admit the form

$$\begin{aligned}\mathcal{R}_\varepsilon(\dot{y}) &= \frac{1}{2} \int_\Omega \int_Q r(\tau_\varepsilon \omega, x) |\dot{y}(\omega, x)|^2 dx dP(\omega), \\ \mathcal{E}_\varepsilon(y) &= \int_\Omega \int_Q V(\tau_\varepsilon \omega, x, \nabla y(\omega, x)) + f(\tau_\varepsilon \omega, x, y(\omega, x)) dx dP(\omega).\end{aligned}$$

Besides usual measurability statements, the main assumptions for $V(\omega, x, \cdot)$ are convexity and p -growth conditions with $p \in (1, \infty)$, and we assume that $f(\omega, x, \cdot)$ has θ -growth with $\theta \in [2, \infty)$ and it is λ -convex, i.e., there exists $\lambda \in \mathbb{R}$ such that $f(\omega, x, \cdot) - \frac{\lambda}{2} |\cdot|^2$ is convex. The latter implies that $\mathcal{E}_\varepsilon(\cdot) - \Lambda \mathcal{R}_\varepsilon(\cdot)$ is convex for suitable $\Lambda \in \mathbb{R}$, i.e., \mathcal{E}_ε is Λ -convex w.r.t. \mathcal{R}_ε . We remark that the rapidly oscillating weight $r(\tau_\varepsilon \omega, x)$ in the dissipation potential represents heterogeneities in the dissipation mechanism of the considered model. We assume that there exists $c > 0$ such that $\frac{1}{c} \leq r \leq c$ a.e. For the precise definitions and assumptions, see Section 2.

The evolution of the gradient flow is described by a state variable $y \in H^1(0, T; Y)$ and it is determined by the following differential inclusion

$$0 \in D\mathcal{R}_\varepsilon(\dot{y}(t)) + \partial_F \mathcal{E}_\varepsilon(y(t)) \quad \text{for a.e. } t \in (0, T), \quad y(0) = y^0 \in Y. \quad (1)$$

Above, $\partial_F \mathcal{E}_\varepsilon : Y \rightarrow 2^{Y^*}$ denotes the Frechét subdifferential (see [26]), which is, in the specific case of a Λ -convex energy \mathcal{E}_ε , given by: $\xi \in \partial_F \mathcal{E}_\varepsilon(y)$ if

$$\mathcal{E}_\varepsilon(y) \leq \mathcal{E}_\varepsilon(\tilde{y}) + \langle \xi, y - \tilde{y} \rangle_{Y^*, Y} - \Lambda \mathcal{R}_\varepsilon(\tilde{y} - y) \quad \text{for all } \tilde{y} \in Y.$$

In this regard, the differential inclusion from (1) is equivalent to the evolutionary variational inequality (EVI)

$$\langle D\mathcal{R}_\varepsilon(\dot{y}(t)), y(t) - \tilde{y} \rangle_{Y^*, Y} \leq \mathcal{E}_\varepsilon(\tilde{y}) - \mathcal{E}_\varepsilon(y(t)) - \Lambda \mathcal{R}_\varepsilon(y(t) - \tilde{y}), \quad (\text{EVI})$$

for all $\tilde{y} \in Y$. We refer to the textbooks [10, 52, 43, 3] for a general and detailed theory of gradient flows. In the simple case $V(\omega, x, F) = A(\omega, x)F \cdot F$ and $f(\omega, x, \alpha) = \alpha^4 - \alpha^2$, (1) corresponds to the weak formulation of an Allen-Cahn equation. Also, in the case that $V(\omega, x, F) = a(\omega, x)|F|^p$ with $p \in (1, \infty)$, the evolution is driven by the p -Laplace operator with oscillatory coefficients.

In the limit $\varepsilon \rightarrow 0$, we derive an effective gradient flow given in terms of a state space $Y_0 = L^2_{\text{inv}}(\Omega) \otimes L^2(Q)$ and homogenized functionals $\mathcal{R}_{\text{hom}} : Y_0 \rightarrow \mathbb{R}$, $\mathcal{E}_{\text{hom}} : Y_0 \rightarrow \mathbb{R} \cup \{\infty\}$. Here $L^2_{\text{inv}}(\Omega) = \{\varphi \in L^2(\Omega) : \varphi(\tau_x \cdot) = \varphi(\cdot) \forall x \in \mathbb{R}^d\}$ is the space of shift-invariant functions, which assuming ergodicity of the probability space boils down to the space of constant functions, i.e. $L^2_{\text{inv}}(\Omega) \simeq \mathbb{R}$. For the precise definitions, see Section 2. In particular, we obtain the following statement for the limit $\varepsilon \rightarrow 0$:

$$\text{If } y_\varepsilon(0) \rightarrow y(0) \text{ strongly in } Y, \quad \mathcal{E}_\varepsilon(y_\varepsilon(0)) \rightarrow \mathcal{E}_{\text{hom}}(y(0)),$$

$$\text{then for all } t \in [0, T], \quad y_\varepsilon(t) \rightarrow y(t) \text{ strongly in } Y, \quad \mathcal{E}_\varepsilon(y_\varepsilon(t)) \rightarrow \mathcal{E}_{\text{hom}}(y(t)),$$

where y_ε and y denote the unique solutions to the gradient flows given in terms of $(Y, \mathcal{E}_\varepsilon, \mathcal{R}_\varepsilon)$ and $(Y_0, \mathcal{E}_{\text{hom}}, \mathcal{R}_{\text{hom}})$, respectively (see Theorem 2.3). Such a statement is called *well-prepared E-convergence* in the terminology of [31], which is an evolutionary Γ -convergence notion.

The proof of this homogenization result relies on a general approach for asymptotic analysis of gradient flows and on the stochastic unfolding procedure, which we briefly explain in the following:

General approach. In the last decades, a number of general strategies for asymptotic analysis of sequences of abstract gradient systems were developed, we refer to [31] for a comprehensive overview. In particular, an early contribution in this field is obtained in [5, 6], where gradient flows on an abstract Hilbert space with fixed dissipation potential $\mathcal{R}_\varepsilon = \mathcal{R}$ and convex energy functionals \mathcal{E}_ε are considered. In this setting, e.g., Mosco convergence $\mathcal{E}_\varepsilon \xrightarrow{M} \mathcal{E}_0$ is sufficient to conclude well-prepared E-convergence. Novel strategies have been developed in [44, 46] and [33], which allow the treatment of very general problems with varying (nonquadratic, convex) dissipation potentials \mathcal{R}_ε and possibly nonconvex energy functionals \mathcal{E}_ε . They are based on *De Giorgi's* $(\mathcal{R}, \mathcal{R}^*)$ formulation (see, e.g., [31, Introduction]). Also, using an integrated version of the (EVI) formulation, in [15] a method for sequences with Λ -convex energies is proposed (see also [30]). In [48], the *Brezis-Ekeland-Nayroles principle* is utilized for the development of a procedure for E-convergence for convex dissipation and energy functionals.

Many approaches for proving E-convergence for problems with *nonconvex* energy functionals rely on the relative compactness in Y of the energy “sublevels” $\{y \in Y : \mathcal{E}_\varepsilon(y) \leq c, \forall \varepsilon\}$ (or a similar strong-type compactness property). In our specific problem (which involves a nonconvex, Λ -convex energy functional) we only have compactness in weak topologies at our disposal. The lack of compactness in a strong topology is due to two reasons. The first reason comes from the fact that we consider convergence in the L^2 -probability space: While in the deterministic periodic case (i.e., when $x \mapsto \tau_x \omega$ is periodic almost surely), the compact embedding $H^1(Q) \subset\subset L^2(Q)$ yields strong compactness of the energy sublevels if $p = 2$, in the general stochastic setting, the embedding of $L^2(\Omega) \otimes H^1(Q)$ into $L^2(\Omega \times Q)$ is not compact. The second reason is a possible mismatch between the growth of f and the growth control via V : If $p < 2$ and d is large, then even in the deterministic periodic case we are not able to obtain a priori strong L^2 -type compactness. For this reason, we consider a modified approach that we briefly describe in the following and we refer to Sections 2 and 4 for details.

We define a new time-dependent energy functional $\tilde{\mathcal{E}}_\varepsilon : [0, T] \times Y \rightarrow \mathbb{R} \cup \{\infty\}$,

$$\tilde{\mathcal{E}}_\varepsilon(t, u) = e^{2\Lambda t} \mathcal{E}_\varepsilon(e^{-\Lambda t} u) - \Lambda \mathcal{R}_\varepsilon(u),$$

for which $\tilde{\mathcal{E}}_\varepsilon(t, \cdot)$ is convex. If y_ε satisfies (EVI) a.e., then using the Fenchel equivalence the new variable $u_\varepsilon(t) := e^{\Lambda t} y_\varepsilon(t)$ fulfills (cf. Lemma 4.1)

$$\langle D\mathcal{R}_\varepsilon(\dot{u}_\varepsilon(t)), u_\varepsilon(t) \rangle_{Y^*, Y} + \tilde{\mathcal{E}}_\varepsilon(t, u_\varepsilon(t)) + \tilde{\mathcal{E}}_\varepsilon^*(t, -D\mathcal{R}_\varepsilon(\dot{u}_\varepsilon(t))) = 0, \quad (2)$$

where $\tilde{\mathcal{E}}_\varepsilon^*(t, \cdot)$ denotes the convex conjugate of $\tilde{\mathcal{E}}_\varepsilon(t, \cdot)$. Using the chain rule and the quadratic structure of \mathcal{R}_ε in form of $(D\mathcal{R}_\varepsilon)^* = D\mathcal{R}_\varepsilon$, we have $\frac{d}{dt} \mathcal{R}_\varepsilon(u_\varepsilon(t)) = \langle D\mathcal{R}_\varepsilon(u_\varepsilon(t)), \dot{u}_\varepsilon(t) \rangle_{Y^*, Y} = \langle D\mathcal{R}_\varepsilon(\dot{u}_\varepsilon(t)), u_\varepsilon(t) \rangle_{Y^*, Y}$. Hence, an integration of (2) over $(0, T)$ yields

$$\mathcal{R}_\varepsilon(u_\varepsilon(T)) + \int_0^T \tilde{\mathcal{E}}_\varepsilon(t, u_\varepsilon(t)) + \tilde{\mathcal{E}}_\varepsilon^*(t, -D\mathcal{R}_\varepsilon(\dot{u}_\varepsilon(t))) dt = \mathcal{R}_\varepsilon(u_\varepsilon(0)). \quad (3)$$

This formulation is equivalent to (EVI) and it is convenient for passing to the limit $\varepsilon \rightarrow 0$ by only using weak convergence of the solution y_ε (resp. u_ε). In fact, (3) is the analogue of the formulation used in the general convex case in [5, 6] with the difference that in our case the energy functionals are time dependent and that the dissipation functionals feature oscillations on scale ε .

Stochastic unfolding. In order to conduct the limit passage $\varepsilon \rightarrow 0$ in (3), we are required to treat objects with random and rapidly oscillating coefficients. For this task, we introduce the *stochastic unfolding method* that allows a straightforward analysis and it presents a random counterpart of the well-established periodic unfolding method.

The notion of periodic two-scale convergence [39, 2] (see also [28]) and the periodic unfolding procedure [13] (see also [14, 50, 34]) are prominent and useful tools in multiscale modeling and homogenization suited for problems involving periodic coefficients. We refer to some of the many problems treated using these methods [28, 12, 21, 34, 35, 32, 27, 22]. In the stochastic setting, the notion of two-scale convergence is generalized in [9] (see also [4, 45]) and in [54] (see also [29, 19, 23]). Yet, as far as we know, the concept of unfolding has not been investigated earlier in the stochastic case.

We extend the idea of the periodic unfolding procedure to the stochastic case. Namely, we introduce a linear isometric operator, the *stochastic unfolding operator*, that enjoys many similarities to the periodic unfolding operator. Also, similarly to the periodic case, stochastic two-scale convergence in the mean from [9] might be equivalently characterized as weak convergence of the unfolded sequence. In this respect, we develop a general procedure for stochastic homogenization problems, see also [49] for a detailed analysis of this method, and [37] for an extension to abstract, linear evolution systems in an operator theoretic framework. Stochastic unfolding has first been introduced by the second and third author in a discrete version in [36] where the discrete-to-continuum limit of a rate-independent evolution is analyzed.

Related results. In the periodic setting homogenization results of this type are obtained for quasilinear parabolic equations, e.g., in [38, 51, 20] (via two-scale convergence and unfolding), for reaction-diffusion systems with different diffusion length scales in [32] (via unfolding), for Cahn-Hilliard type gradient flows in [27] (via unfolding). In the stochastic case, parabolic type equations are treated in [53, 16, 24, 17]. However, the approach we consider is different, it relies on the more general gradient flow formulation and we do not rely on differentiability of the integrands V and f and on continuity assumptions on their derivatives.

Structure of the paper. In Section 2 we present the main stochastic homogenization result of this paper. Section 3 is dedicated to the introduction of the stochastic unfolding procedure. In Section 4 we present the proof of the main Theorem 2.3.

Notation. (Ω, \mathcal{F}, P) denotes a complete and separable probability space, the corresponding mathematical expectation is denoted by $\langle \cdot \rangle = \int_{\Omega} \cdot dP(\omega)$. For $Q \subset \mathbb{R}^d$ open, we denote by $\mathcal{L}(Q)$ the Lebesgue σ -algebra. For a Banach space X , its dual space is denoted by X^* and the Borel σ -algebra on X is given by $\mathcal{B}(X)$. For $p \in (1, \infty)$, $L^p(\Omega)$ and $L^p(Q)$ are the usual Banach spaces of p -integrable functions defined on (Ω, \mathcal{F}, P) and Q , respectively. We introduce function spaces for functions defined on $\Omega \times Q$ as follows: For closed subspaces $X \subset L^p(\Omega)$ and $Z \subset L^p(Q)$, we denote by $X \otimes Z$ the closure of

$$X \overset{a}{\otimes} Z := \left\{ \sum_{i=1}^n \varphi_i \eta_i : \varphi_i \in X, \eta_i \in Z, n \in \mathbb{N} \right\}$$

in $L^p(\Omega \times Q)$. Note that in the case $X = L^p(\Omega)$ and $Z = L^p(Q)$, we have $X \otimes Z = L^p(\Omega \times Q)$. Up to isometric isomorphisms, we may identify $L^p(\Omega \times Q)$ with the

Bochner spaces $L^p(\Omega; L^p(Q))$ and $L^p(Q; L^p(\Omega))$. Slightly abusing the notation, for closed subspaces $X \subset L^p(\Omega)$ and $Z \subset W^{1,p}(Q)$, we denote by $X \otimes Z$ the closure of

$$X \overset{a}{\otimes} Z := \left\{ \sum_{i=1}^n \varphi_i \eta_i : \varphi_i \in X, \eta_i \in Z, n \in \mathbb{N} \right\}$$

in $L^p(\Omega; W^{1,p}(Q))$. In this regard, we may identify $u \in L^p(\Omega) \otimes W^{1,p}(Q)$ with the pair $(u, \nabla u) \in L^p(\Omega \times Q)^{1+d}$. We mostly focus on the space $L^p(\Omega \times Q)$ and the above notation is convenient for keeping track of its various subspaces.

2. Homogenization of gradient flows. First, we briefly recall the standard functional analytic setting for stochastic homogenization introduced by Papanicolaou and Varadhan in [40] (see also [25]). In the second part of this section we present the main homogenization result. We start with a motivation for the below abstract setting. In stochastic homogenization coefficients of equations are assumed to be random and can be viewed as a family of random variables, say $\{a(x)\}_{x \in \mathbb{R}^d}$. Minimal assumptions required for stochastic homogenization are *stationarity* and *ergodicity*. Stationarity means that the coefficients are statistically homogeneous: for any finite number of points x_1, \dots, x_n the joint distribution of $(a(x_1 + z), \dots, a(x_n + z))$ is independent of the shift $z \in \mathbb{R}^d$. On the other hand, ergodicity means that long-range correlations become negligible on large scales. As shown in [40], if the random field $\{a(x)\}_{x \in \mathbb{R}^d}$ is stochastically continuous, then the above can be rephrased in the following functional analytic setting: There exists a probability space (Ω, \mathcal{F}, P) , where Ω denotes a set of parameter fields on \mathbb{R}^d , say $\Omega := \{\omega : \mathbb{R}^d \rightarrow \mathbb{R} \text{ measurable}\}$, and \mathcal{F} and P are constructed according to [40]. We can equip Ω with a natural shift operator $\tau_x : \Omega \rightarrow \Omega$, $\tau_x \omega(y) = \omega(y - x)$. The notion of stationarity and ergodicity can now be defined with help of τ , see below. In this setting stationary and ergodic coefficients, say for an elliptic PDE of the form $-\nabla \cdot (a_\varepsilon(x) \nabla u) = f$, are described by a random variable $a_0 : \Omega \rightarrow \mathbb{R}^{d \times d}$ with $a_0 \in L^\infty(\Omega)$ being uniformly positive-definite, and setting $a_\varepsilon(x) = a_0(\tau_{\frac{x}{\varepsilon}} \omega)$, where ω is distributed according to P . The parameter $\varepsilon > 0$ describes the length scale of the “typical correlations”. A simple example is a random checkerboard, where $\omega \in \Omega$ is of the form

$$\omega(x) = \sum_{z \in \mathbb{Z}^d} \mathbf{1}_{z+[0,1)^d}(x - y) \omega_z,$$

with y a $[0, 1)^d$ -valued random variable and $\{\omega_z\}_{z \in \mathbb{Z}^d}$ a family of independent and identically distributed random variables. In that case a_ε is a stationary random coefficient field that is uncorrelated on scales larger than ε .

Assumption 2.1. Let (Ω, \mathcal{F}, P) be a complete and separable probability space. Let $\tau = \{\tau_x\}_{x \in \mathbb{R}^d}$ denote a group of invertible measurable mappings $\tau_x : \Omega \rightarrow \Omega$ such that:

- (i) (Group property). $\tau_0 = Id$ and $\tau_{x+y} = \tau_x \circ \tau_y$ for all $x, y \in \mathbb{R}^d$.
- (ii) (Measure preservation). $P(\tau_x E) = P(E)$ for all $E \in \mathcal{F}$ and $x \in \mathbb{R}^d$.
- (iii) (Measurability). $(\omega, x) \mapsto \tau_x \omega$ is $(\mathcal{F} \otimes \mathcal{L}(\mathbb{R}^d), \mathcal{F})$ -measurable.

Throughout the paper we assume that $(\Omega, \mathcal{F}, P, \tau)$ satisfies Assumption 2.1. The separability assumption on the measure space implies that $L^p(\Omega)$ is separable. We say that $(\Omega, \mathcal{F}, P, \tau)$ is *ergodic* ($\langle \cdot \rangle$ is ergodic), if

every shift invariant $E \in \mathcal{F}$ (i.e., $\tau_x E = E$ for all $x \in \mathbb{R}^d$) satisfies $P(E) \in \{0, 1\}$.

We introduce two auxiliary subspaces of $L^p(\Omega)$ that are important for the homogenization procedure. We consider the group of isometric operators $\{U_x\}_{x \in \mathbb{R}^d}$, $U_x : L^p(\Omega) \rightarrow L^p(\Omega)$ defined by $U_x \varphi(\omega) = \varphi(\tau_x \omega)$, which is strongly continuous (the argument for this fact can be found in [25, Section 7.1]). For $i = 1, \dots, d$, we consider the one-parameter group of operators $\{U_{he_i}\}_{h \in \mathbb{R}}$ ($\{e_i\}$ being the usual basis of \mathbb{R}^d) and its infinitesimal generator $D_i : \mathcal{D}_i \subset L^p(\Omega) \rightarrow L^p(\Omega)$,

$$D_i \varphi = \lim_{h \rightarrow 0} \frac{U_{he_i} \varphi - \varphi}{h},$$

which we refer to as the *stochastic derivative*. D_i is a linear and closed operator and its domain \mathcal{D}_i is dense in $L^p(\Omega)$ (see, e.g., [18, Section 7.4]). We set $W^{1,p}(\Omega) = \cap_{i=1}^d \mathcal{D}_i$ and define for $\varphi \in W^{1,p}(\Omega)$ the *stochastic gradient* as $D\varphi = (D_1\varphi, \dots, D_d\varphi)$. In this manner, we obtain a linear, closed and densely defined operator $D : W^{1,p}(\Omega) \rightarrow L^p(\Omega)^d$, and we denote by

$$L_{\text{pot}}^p(\Omega) := \overline{\text{ran}(D)} \subset L^p(\Omega)^d$$

the closure of the range of D in $L^p(\Omega)^d$. We denote the adjoint of D by $D^* : \mathcal{D}^* \subset L^q(\Omega)^d \rightarrow L^q(\Omega)$ which is a linear, closed and densely defined operator (see, e.g., [11, Section 2.6]), \mathcal{D}^* denotes the domain of D^* and $q = \frac{p}{p-1}$. Note that $W^{1,q}(\Omega)^d \subset \mathcal{D}^*$ and for all $\varphi \in W^{1,p}(\Omega)$ and $\psi \in W^{1,q}(\Omega)$ we have the integration by parts formula, $i = 1, \dots, d$,

$$\langle \psi D_i \varphi \rangle = - \langle \varphi D_i \psi \rangle, \quad (4)$$

and thus $D^* \psi = - \sum_{i=1}^d D_i \psi_i$ for $\psi \in W^{1,q}(\Omega)^d$. We define the subspace of *shift-invariant functions* in $L^p(\Omega)$ by

$$L_{\text{inv}}^p(\Omega) = \{ \varphi \in L^p(\Omega) : U_x \varphi = \varphi \text{ for all } x \in \mathbb{R}^d \},$$

and denote by $P_{\text{inv}} : L^p(\Omega) \rightarrow L_{\text{inv}}^p(\Omega)$ the conditional expectation with respect to the σ -algebra of shift invariant sets $\{E \in \mathcal{F} : \tau_x E = E \text{ for all } x \in \mathbb{R}^d\}$. P_{inv} is a contractive projection and for $p = 2$ it coincides with the orthogonal projection onto $L_{\text{inv}}^2(\Omega)$. Also, if $\langle \cdot \rangle$ is ergodic, then it holds $L_{\text{inv}}^p(\Omega) \simeq \mathbb{R}$ and $P_{\text{inv}} \varphi = \langle \varphi \rangle$.

Heterogeneous system. Let $Q \subset \mathbb{R}^d$ be open and bounded. Let $p \in (1, \infty)$ and $\theta \in [2, \infty)$. The system that we consider is defined on a state space

$$Y = L^2(\Omega \times Q).$$

The dissipation functional is given by $\mathcal{R}_\varepsilon : Y \rightarrow [0, \infty)$,

$$\mathcal{R}_\varepsilon(\dot{y}) = \frac{1}{2} \left\langle \int_Q r(\tau_{\frac{x}{\varepsilon}} \omega, x) |\dot{y}(\omega, x)|^2 dx \right\rangle.$$

The energy functional $\mathcal{E}_\varepsilon : Y \rightarrow \mathbb{R} \cup \{\infty\}$ is defined as

$$\mathcal{E}_\varepsilon(y) = \left\langle \int_Q V(\tau_{\frac{x}{\varepsilon}} \omega, x, \nabla y(\omega, x)) + f(\tau_{\frac{x}{\varepsilon}} \omega, x, y(\omega, x)) dx \right\rangle,$$

for $y \in (L^p(\Omega) \otimes W_0^{1,p}(Q)) \cap L^\theta(\Omega \times Q) =: \text{dom}(\mathcal{E}_\varepsilon)$ and $\mathcal{E}_\varepsilon = \infty$ otherwise. Above, $r : \Omega \times Q \rightarrow \mathbb{R}$, $V : \Omega \times Q \times \mathbb{R}^d \rightarrow \mathbb{R}$ and $f : \Omega \times Q \times \mathbb{R} \rightarrow \mathbb{R}$ and we consider the following assumptions: There exists $c > 0$ such that:

(A1) r is $\mathcal{F} \otimes \mathcal{L}(Q)$ -measurable and for a.e. $(\omega, x) \in \Omega \times Q$, we have $\frac{1}{c} \leq r(\omega, x) \leq c$.

(A2) $V(\cdot, \cdot, F)$ is $\mathcal{F} \otimes \mathcal{L}(Q)$ -measurable for all $F \in \mathbb{R}^d$, $V(\omega, x, \cdot)$ is convex for a.e. $(\omega, x) \in \Omega \times Q$ and

$$\frac{1}{c}|F|^p - c \leq V(\omega, x, F) \leq c(|F|^p + 1) \quad (5)$$

for a.e. $(\omega, x) \in \Omega \times Q$ and all $F \in \mathbb{R}^d$.

(A3) $f(\cdot, \cdot, \alpha)$ is $\mathcal{F} \otimes \mathcal{L}(Q)$ -measurable for all $\alpha \in \mathbb{R}$. There exists $\lambda \in \mathbb{R}$ such that for a.e. $(\omega, x) \in \Omega \times Q$

$$\begin{aligned} f(\omega, x, \cdot) \text{ is } \lambda\text{-convex, i.e., } \alpha \mapsto f(\omega, x, \alpha) - \frac{\lambda}{2}|\alpha|^2 \text{ is convex,} \\ \frac{1}{c}|\alpha|^\theta - c \leq f(\omega, x, \alpha) \leq c(|\alpha|^\theta + 1) \quad \text{for all } \alpha \in \mathbb{R}. \end{aligned} \quad (6)$$

We remark that the above assumptions imply that there exists $\Lambda \in \mathbb{R}$ such that $y \mapsto \mathcal{E}_\varepsilon(y) - \Lambda \mathcal{R}_\varepsilon(y)$ is convex, i.e. \mathcal{E}_ε is Λ -convex w.r.t. \mathcal{R}_ε . In particular, if $\lambda < 0$, then we set $\Lambda = \lambda c$, and in the case $\lambda \geq 0$, $\Lambda = \frac{\lambda}{c}$.

Let $T > 0$ be a finite time horizon. We consider the evolutionary variational inequality (EVI) formulation of the gradient flow $(Y, \mathcal{E}_\varepsilon, \mathcal{R}_\varepsilon)$: Find $y \in H^1(0, T; Y)$ such that for a.e. $t \in (0, T)$,

$$\langle D\mathcal{R}_\varepsilon(\dot{y}(t)), y(t) - \tilde{y} \rangle_{Y^*, Y} \leq \mathcal{E}_\varepsilon(\tilde{y}) - \mathcal{E}_\varepsilon(y(t)) - \Lambda \mathcal{R}_\varepsilon(y(t) - \tilde{y}) \quad \text{for all } \tilde{y} \in Y. \quad (7)$$

Remark 2.2 (Existence and uniqueness). Assumptions (A1)-(A3) imply that \mathcal{E}_ε is proper, l.s.c., coercive and Λ -convex w.r.t. \mathcal{R}_ε . In this respect, the classical theory of maximal monotone operators with Lipschitz perturbations implies that for an initial datum $y^0 \in \text{dom}(\mathcal{E}_\varepsilon)$, there exists a unique $y \in H^1(0, T; Y)$ which satisfies (7) and $y(0) = y^0$, see [10, Proposition 3.12], [7, Theorem 4.4], where the *Yosida regularization* technique is used for the proof of this result. In view of the continuous embedding $H^1(0, T; Y) \subset C([0, T], Y)$, we identify functions in $H^1(0, T; Y)$ by their continuous representatives. Moreover, the following standard apriori estimate holds

$$2 \int_0^t \mathcal{R}_\varepsilon(\dot{y}(s)) ds \leq \mathcal{E}_\varepsilon(y^0) - \mathcal{E}_\varepsilon(y(t)) \quad \text{for all } t \in [0, T], \quad (8)$$

which follows by testing (1) with $\dot{y}(s)$ and by the chain rule for the Λ -convex functional \mathcal{E}_ε . (8) in combination with the growth conditions (5) and (6) yields

$$\|y(t)\|_{L^p(\Omega) \otimes W_0^{1,p}(Q)}^p + \|y(t)\|_{L^\theta(\Omega \times Q)}^\theta \leq c(\mathcal{E}_\varepsilon(y^0) + 2c). \quad (9)$$

Effective system. In the limit $\varepsilon \rightarrow 0$, we derive an effective gradient flow which is described as follows. The state space is given by

$$Y_0 = L_{\text{inv}}^2(\Omega) \otimes L^2(Q).$$

The effective dissipation potential is given by $\mathcal{R}_{\text{hom}} : Y_0 \rightarrow [0, \infty)$,

$$\mathcal{R}_{\text{hom}}(\dot{y}) = \left\langle \int_Q r(\omega, x) |\dot{y}(\omega, x)|^2 dx \right\rangle.$$

The energy functional is $\mathcal{E}_{\text{hom}} : Y_0 \rightarrow \mathbb{R} \cup \{\infty\}$,

$$\begin{aligned} \mathcal{E}_{\text{hom}}(y) = \inf_{\chi \in L_{\text{pot}}^p(\Omega) \otimes L^p(Q)} \left\langle \int_Q V(\omega, x, \nabla y(\omega, x) + \chi(\omega, x)) dx \right\rangle \\ + \left\langle \int_Q f(\omega, x, y(\omega, x)) dx \right\rangle \end{aligned} \quad (10)$$

for $y \in (L_{\text{inv}}^p(\Omega) \otimes W_0^{1,p}(Q)) \cap (L_{\text{inv}}^\theta(\Omega) \otimes L^\theta(Q)) =: \text{dom}(\mathcal{E}_{\text{hom}})$ and $\mathcal{E}_{\text{hom}} = \infty$ otherwise. We remark that $\mathcal{E}_{\text{hom}}(\cdot) - \Lambda \mathcal{R}_{\text{hom}}(\cdot)$ is convex with the same $\Lambda \in \mathbb{R}$ as for \mathcal{E}_ε .

The gradient flow $(Y_0, \mathcal{E}_{\text{hom}}, \mathcal{R}_{\text{hom}})$ in the EVI formulation also admits a unique solution, i.e., for an initial datum $y^0 \in \text{dom}(\mathcal{E}_{\text{hom}})$, there exists a unique $y \in H^1(0, T; Y_0)$ such that $y(0) = y^0$ and for a.e. $t \in (0, T)$,

$$\langle D\mathcal{R}_{\text{hom}}(\dot{y}(t)), y(t) - \tilde{y} \rangle_{Y_0^*, Y_0} \leq \mathcal{E}_{\text{hom}}(\tilde{y}) - \mathcal{E}_{\text{hom}}(y(t)) - \Lambda \mathcal{R}_{\text{hom}}(y(t) - \tilde{y}), \quad (11)$$

for all $\tilde{y} \in Y_0$.

The main result of this paper is the following homogenization theorem. In particular, the proof relies on the modified abstract strategy discussed in the introduction and on the stochastic unfolding procedure that is explained in Section 3.

Theorem 2.3 (Homogenization). *Let $p \in (1, \infty)$, $\theta \in [2, \infty)$ and $Q \subset \mathbb{R}^d$ be open and bounded. Assume (A1)-(A3), and consider $y^0 \in \text{dom}(\mathcal{E}_{\text{hom}})$, $y_\varepsilon^0 \in \text{dom}(\mathcal{E}_\varepsilon)$ such that, as $\varepsilon \rightarrow 0$,*

$$y_\varepsilon^0 \rightarrow y^0 \quad \text{strongly in } Y, \quad \limsup_{\varepsilon \rightarrow 0} \mathcal{E}_\varepsilon(y_\varepsilon^0) < \infty.$$

Let $y_\varepsilon \in H^1(0, T; Y)$ be the unique solution to the EVI (7) with $y_\varepsilon(0) = y_\varepsilon^0$. Then, for all $t \in (0, T]$, as $\varepsilon \rightarrow 0$,

$$y_\varepsilon(t) \rightarrow y(t) \quad \text{strongly in } Y,$$

where $y \in H^1(0, T; Y_0)$ is the unique solution to the EVI (11) with $y(0) = y^0$. Moreover, if we additionally assume that $\mathcal{E}_\varepsilon(y_\varepsilon^0) \rightarrow \mathcal{E}_{\text{hom}}(y^0)$, then it holds that $\dot{y}_\varepsilon \rightarrow \dot{y}$ strongly in $L^2(0, T; Y)$ and $\mathcal{E}_\varepsilon(y_\varepsilon(t)) \rightarrow \mathcal{E}_{\text{hom}}(y(t))$ for all $t \in [0, T]$. (For the proof see Section 4.)

Remark 2.4 (Convergence of gradients). We remark that in the proof we additionally show that $y_\varepsilon(t) \xrightarrow{2} y(t)$ in $L^\theta(\Omega \times Q)$ and in $L^p(\Omega \times Q)$, where “ $\xrightarrow{2}$ ” is weak stochastic two-scale convergence in the mean defined in Definition 3.2. Also, it holds $P_{\text{inv}} \nabla y_\varepsilon(t) \rightharpoonup \nabla y(t)$ weakly in $L^p(\Omega \times Q)^d$. If we additionally assume that $V(\omega, x, \cdot)$ is strictly convex, we may obtain that for all $t \in (0, T]$ it holds

$$\nabla y_\varepsilon(t) \xrightarrow{2} \nabla y(t) + \chi(t) \quad \text{in } L^p(\Omega \times Q)^d,$$

where $\chi(t) \in L_{\text{pot}}^p(\Omega) \otimes L^p(Q)$ is the unique minimizer in the corrector problem

$$\inf_{\chi \in L_{\text{pot}}^p(\Omega) \otimes L^p(Q)} \left\langle \int_Q V(\omega, x, \nabla y(t, \omega, x) + \chi(\omega, x)) dx \right\rangle.$$

Remark 2.5 (Ergodic case). If we additionally assume that $\langle \cdot \rangle$ is ergodic, the limit system is driven by deterministic functionals. In particular, the state space reduces to $Y_0 = L^2(Q)$. The dissipation potential is given by

$$\mathcal{R}_{\text{hom}}(\dot{y}) = \int_Q r_{\text{hom}}(x) |\dot{y}(x)|^2 dx,$$

where $r_{\text{hom}}(x) = \langle r(\omega, x) \rangle$. The energy functional boils down to

$$\mathcal{E}_{\text{hom}}(y) = \int_Q V_{\text{hom}}(x, \nabla y(x)) + f_{\text{hom}}(x, y(x)) dx$$

in $W_0^{1,p}(Q) \cap L^\theta(Q)$ and otherwise ∞ . Above, $f_{\text{hom}}(x, \alpha) = \langle f(\omega, x, \alpha) \rangle$ for $x \in Q$ and $\alpha \in \mathbb{R}$, and $V_{\text{hom}}(x, F) = \inf_{\chi \in L_{\text{pot}}^p(\Omega)} \langle V(x, \omega, F + \chi(\omega)) \rangle$ for $x \in Q$, $F \in \mathbb{R}^d$.

Moreover, V_{hom} satisfies analogous p -growth conditions as V . The identification of \mathcal{E}_{hom} can be obtained by a measurable selection argument from Remark A.5 (cf. proof of Lemma 4.4).

3. Stochastic unfolding method. In this section we introduce the stochastic unfolding method. In particular, in Section 3.1 we define the unfolding operator and present its main properties. In Section 3.2 we obtain weak two-scale type compactness statements and we construct suitable recovery sequences. To keep the exposition simple, the proofs are presented in the end, in Section 3.3.

3.1. Stochastic unfolding operator and two-scale convergence in the mean. We recall that we generally assume Assumption 2.1.

Lemma 3.1. *Let $\varepsilon > 0$, $p \in (1, \infty)$, $q = \frac{p}{p-1}$, and $Q \subset \mathbb{R}^d$ be open. There exists a unique linear isometric isomorphism*

$$\mathcal{T}_\varepsilon : L^p(\Omega \times Q) \rightarrow L^p(\Omega \times Q)$$

which satisfies

$$\text{for all } u \in L^p(\Omega) \overset{a}{\otimes} L^p(Q), \quad (\mathcal{T}_\varepsilon u)(\omega, x) = u(\tau_{-\frac{x}{\varepsilon}}\omega, x) \quad \text{a.e. in } \Omega \times Q.$$

Moreover, its adjoint is the unique linear isometric isomorphism $\mathcal{T}_\varepsilon^* : L^q(\Omega \times Q) \rightarrow L^q(\Omega \times Q)$ that satisfies for all $u \in L^q(\Omega) \overset{a}{\otimes} L^q(Q)$, $(\mathcal{T}_\varepsilon^* u)(\omega, x) = u(\tau_{\frac{x}{\varepsilon}}\omega, x)$ a.e. in $\Omega \times Q$.

(For the proof see Section 3.3.)

Definition 3.2 (Unfolding operator and two-scale convergence in the mean). The operator $\mathcal{T}_\varepsilon : L^p(\Omega \times Q) \rightarrow L^p(\Omega \times Q)$ from Lemma 3.1 is called the stochastic unfolding operator. We say that a sequence $(u_\varepsilon) \subset L^p(\Omega \times Q)$ weakly (strongly) two-scale converges in the mean in $L^p(\Omega \times Q)$ to $u \in L^p(\Omega \times Q)$ if, as $\varepsilon \rightarrow 0$,

$$\mathcal{T}_\varepsilon u_\varepsilon \rightarrow u \quad \text{weakly (strongly) in } L^p(\Omega \times Q).$$

In this case we write $u_\varepsilon \xrightarrow{2} u$ (resp. $u_\varepsilon \xrightarrow{2} u$) in $L^p(\Omega \times Q)$.

Remark 3.3 (A technical remark about measurability). We remark that an element $u \in L^p(\Omega \times Q)$ is an $\overline{\mathcal{F} \otimes \mathcal{L}(Q)}$ -measurable function, i.e., measurable w.r.t. the $P \otimes dx$ -completion of the product σ -algebra $\mathcal{F} \otimes \mathcal{L}(Q)$. On the other hand, the transformation $T_\varepsilon : (\omega, x) \mapsto (\tau_{-\frac{x}{\varepsilon}}\omega, x)$ is $(\mathcal{F} \otimes \mathcal{L}(Q), \mathcal{F} \otimes \mathcal{L}(Q))$ -measurable. In this respect, a priori the composition $(u \circ T_\varepsilon)(\omega, x) = u(\tau_{-\frac{x}{\varepsilon}}\omega, x)$ does not necessarily define an $\overline{\mathcal{F} \otimes \mathcal{L}(Q)}$ -measurable function. We avoid the (fruitless) discussion of such measurability issues by defining the unfolding operator on a dense subset of $L^p(\Omega \times Q)$ (where measurability is clear) and by extending it to the entire space.

The below lemma directly follows from the isometry property of \mathcal{T}_ε and the usual properties of weak and strong convergence in $L^p(\Omega \times Q)$, where we also use the fact that L^p -spaces are uniformly convex for $p \in (1, \infty)$. Therefore, we do not present its proof.

Lemma 3.4 (Basic properties). *Let $p \in (1, \infty)$, $q = \frac{p}{p-1}$ and $Q \subset \mathbb{R}^d$ be open. Consider sequences (u_ε) in $L^p(\Omega \times Q)$ and (v_ε) in $L^q(\Omega \times Q)$.*

(i) *If $u_\varepsilon \xrightarrow{2} u$ in $L^p(\Omega \times Q)$, then $\limsup_{\varepsilon \rightarrow 0} \|u_\varepsilon\|_{L^p(\Omega \times Q)} < \infty$ and*

$$\|u\|_{L^p(\Omega \times Q)} \leq \liminf_{\varepsilon \rightarrow 0} \|u_\varepsilon\|_{L^p(\Omega \times Q)}.$$

- (ii) If $\limsup_{\varepsilon \rightarrow 0} \|u_\varepsilon\|_{L^p(\Omega \times Q)} < \infty$, then there exist a subsequence ε' and $u \in L^p(\Omega \times Q)$ such that $u_{\varepsilon'} \xrightarrow{2} u$ in $L^p(\Omega \times Q)$.
- (iii) $u_\varepsilon \xrightarrow{2} u$ in $L^p(\Omega \times Q)$ if and only if $u_\varepsilon \xrightarrow{2} u$ in $L^p(\Omega \times Q)$ and $\|u_\varepsilon\|_{L^p(\Omega \times Q)} \rightarrow \|u\|_{L^p(\Omega \times Q)}$.
- (iv) If $u_\varepsilon \xrightarrow{2} u$ in $L^p(\Omega \times Q)$ and $v_\varepsilon \xrightarrow{2} v$ in $L^q(\Omega \times Q)$, then

$$\left\langle \int_Q u_\varepsilon(\omega, x) v_\varepsilon(\omega, x) dx \right\rangle \rightarrow \left\langle \int_Q u(\omega, x) v(\omega, x) dx \right\rangle.$$

For homogenization of variational problems, in particular problems driven by convex integral functionals, the following transformation and (lower semi-)continuity properties are very useful.

Proposition 3.5. *Let $p \in (1, \infty)$ and $Q \subset \mathbb{R}^d$ be open and bounded. Let $V : \Omega \times Q \times \mathbb{R}^m \rightarrow \mathbb{R}$ be such that $V(\cdot, \cdot, F)$ is $\mathcal{F} \otimes \mathcal{L}(Q)$ -measurable for all $F \in \mathbb{R}^m$ and $V(\omega, x, \cdot)$ is continuous for a.e. $(\omega, x) \in \Omega \times Q$. Also, we assume that there exists $c > 0$ such that for a.e. $(\omega, x) \in \Omega \times Q$*

$$|V(\omega, x, F)| \leq c(1 + |F|^p), \quad \text{for all } F \in \mathbb{R}^m.$$

Then the following statements hold:

- (i) For all $u \in L^p(\Omega \times Q)^m$, we have

$$\left\langle \int_Q V(\tau_{\frac{x}{\varepsilon}} \omega, x, u(\omega, x)) dx \right\rangle = \left\langle \int_Q V(\omega, x, \mathcal{T}_\varepsilon u(\omega, x)) dx \right\rangle. \quad (12)$$

- (ii) If $u_\varepsilon \xrightarrow{2} u$ in $L^p(\Omega \times Q)^m$, then

$$\lim_{\varepsilon \rightarrow 0} \left\langle \int_Q V(\tau_{\frac{x}{\varepsilon}} \omega, x, u_\varepsilon(\omega, x)) dx \right\rangle = \left\langle \int_Q V(\omega, x, u(\omega, x)) dx \right\rangle.$$

- (iii) We additionally assume that for a.e. $(\omega, x) \in \Omega \times Q$, $V(\omega, x, \cdot)$ is convex. Then, if $u_\varepsilon \xrightarrow{2} u$ in $L^p(\Omega \times Q)^m$,

$$\liminf_{\varepsilon \rightarrow 0} \left\langle \int_Q V(\tau_{\frac{x}{\varepsilon}} \omega, x, u_\varepsilon(\omega, x)) dx \right\rangle \geq \left\langle \int_Q V(\omega, x, u(\omega, x)) dx \right\rangle.$$

(For the proof see Section 3.3.)

Remark 3.6 (Comparison to the notion of [9]). The notion of weak two-scale convergence in the mean of Definition 3.2, i.e., weak convergence of unfolded sequences, coincides with the convergence notion introduced in [9] (see also [4]). More precisely, for a bounded sequence $(u_\varepsilon) \subset L^p(\Omega \times Q)$ we have $u_\varepsilon \xrightarrow{2} u$ in $L^p(\Omega \times Q)$ (in the sense of Definition 3.2) if and only if u_ε stochastically two-scale converges in the mean to u in the sense of [9], i.e.

$$\lim_{\varepsilon \rightarrow 0} \left\langle \int_Q u_\varepsilon(\omega, x) \varphi(\tau_{\frac{x}{\varepsilon}} \omega, x) dx \right\rangle = \left\langle \int_Q u(\omega, x) \varphi(\omega, x) dx \right\rangle, \quad (13)$$

for any $\varphi \in L^q(\Omega \times Q)$ that is admissible (in the sense that the mapping $(\omega, x) \mapsto \varphi(\tau_{\frac{x}{\varepsilon}} \omega, x)$ is well-defined). Indeed, with help of \mathcal{T}_ε (and its adjoint) we might rephrase the integral on the left-hand side in (13) as

$$\left\langle \int_Q u_\varepsilon(\mathcal{T}_\varepsilon^* \varphi) dx \right\rangle = \left\langle \int_Q (\mathcal{T}_\varepsilon u_\varepsilon) \varphi dx \right\rangle, \quad (14)$$

which proves the equivalence. For the reason of this equivalence, we use the terms *weak* and *strong stochastic two-scale convergence in the mean* instead of talking about *weak* or *strong convergence of unfolded sequences*.

The arguments in this paper are inspired by both, the *unfolding approach*—we transform integrals with oscillations into integrals without (or controllable) oscillations—and *two-scale convergence* in the sense that we make use of oscillating test-functions.

3.2. Two-scale limits of gradients. The following proposition presents a weak two-scale compactness statement for sequences of gradient fields.

Proposition 3.7 (Compactness). *Let $p \in (1, \infty)$ and $Q \subset \mathbb{R}^d$ be open. Let (u_ε) be a bounded sequence in $L^p(\Omega) \otimes W^{1,p}(Q)$. Then, there exist $u \in L^p_{\text{inv}}(\Omega) \otimes W^{1,p}(Q)$ and $\chi \in L^p_{\text{pot}}(\Omega) \otimes L^p(Q)$ such that, up to a subsequence,*

$$u_\varepsilon \xrightarrow{2} u \quad \text{in } L^p(\Omega \times Q), \quad \nabla u_\varepsilon \xrightarrow{2} \nabla u + \chi \quad \text{in } L^p(\Omega \times Q)^d. \quad (15)$$

If, additionally, $\langle \cdot \rangle$ is ergodic, then $u = P_{\text{inv}} u = \langle u \rangle \in W^{1,p}(Q)$ and $\langle u_\varepsilon \rangle \rightharpoonup u$ weakly in $W^{1,p}(Q)$.

(For the proof see Section 3.3.)

We remark that the above result is already established in [9] in the context of two-scale convergence in the mean in the L^2 -space setting. We recapitulate its short proof from the perspective of stochastic unfolding, see Section 3.3.

Remark 3.8. Note that the proof of the above proposition reveals that $P_{\text{inv}} u_\varepsilon \rightharpoonup u$ weakly in $L^p_{\text{inv}}(\Omega) \otimes W^{1,p}(Q)$ (see Lemma 3.13). If we consider a closed subspace $X \subset W^{1,p}(Q)$ and assume that $u_\varepsilon(\omega) \in X$ P -a.e., then $P_{\text{inv}} u_\varepsilon \in L^p_{\text{inv}}(\Omega) \otimes X$. Therefore, it follows that $u \in L^p_{\text{inv}}(\Omega) \otimes X$. This observation is useful if we consider boundary value problems, e.g., if $X = W_0^{1,p}(Q)$. We may argue similarly for closed convex subsets in $W^{1,p}(Q)$.

Lemma 3.9 (Recovery sequence). *Let $p, \theta \in (1, \infty)$ and $Q \subset \mathbb{R}^d$ be open. For $\chi \in L^p_{\text{pot}}(\Omega) \otimes L^p(Q)$ and $\delta > 0$, there exists a sequence $g_{\delta,\varepsilon}(\chi) \in L^p(\Omega) \otimes W_0^{1,p}(Q)$ such that*

$$\|g_{\delta,\varepsilon}(\chi)\|_{L^\theta(\Omega \times Q)} \leq \varepsilon c(\delta), \quad \limsup_{\varepsilon \rightarrow 0} \|\mathcal{T}_\varepsilon \nabla g_{\delta,\varepsilon}(\chi) - \chi\|_{L^p(\Omega \times Q)^d} \leq \delta,$$

where $c(\delta) > 0$ does not depend on ε .

(For the proof see Section 3.3.)

3.3. Proofs of the statements in section 3. Before presenting the proofs, we recall some basic facts from functional analysis which will be helpful in the following.

Remark 3.10. Let $p \in (1, \infty)$ and $q = \frac{p}{p-1}$.

- (i) $\langle \cdot \rangle$ is ergodic $\Leftrightarrow L^p_{\text{inv}}(\Omega) \simeq \mathbb{R} \Leftrightarrow P_{\text{inv}} f = \langle f \rangle$.
- (ii) The following orthogonality relations hold (for a proof see [11, Section 2.6]): We identify the dual space $L^p(\Omega)^*$ with $L^q(\Omega)$, and define for a set $A \subset L^q(\Omega)$ its orthogonal complement $A^\perp \subset L^p(\Omega)$ as

$$A^\perp = \{\varphi \in L^p(\Omega) : \langle \varphi, \psi \rangle = 0 \text{ for all } \psi \in A\}.$$

It holds

$$\ker(D) = \text{ran}(D^*)^\perp, \quad L^p_{\text{pot}}(\Omega) = \overline{\text{ran}(D)} = \ker(D^*)^\perp. \quad (16)$$

Above, $\ker(\cdot)$ denotes the kernel and $\text{ran}(\cdot)$ the range of an operator.

Proof of Lemma 3.1. We first define an operator $\mathcal{T}_\varepsilon : L^p(\Omega) \overset{a}{\otimes} L^p(Q) \rightarrow L^p(\Omega \times Q)$: For $u = \sum_i \varphi_i \eta_i \in L^p(\Omega) \overset{a}{\otimes} L^p(Q)$ with $\varphi_i \in L^p(\Omega)$ and $\eta_i \in L^p(Q)$, let

$$(\mathcal{T}_\varepsilon u)(\omega, x) = \sum_i \varphi_i(\tau_{-\frac{x}{\varepsilon}} \omega) \eta_i(x) = u(\tau_{-\frac{x}{\varepsilon}} \omega, x).$$

\mathcal{T}_ε is a linear operator which is isometric by the following observation: For $u \in L^p(\Omega) \overset{a}{\otimes} L^p(Q)$,

$$\|\mathcal{T}_\varepsilon u\|_{L^p(\Omega \times Q)}^p = \int_Q \langle |u(\tau_{-\frac{x}{\varepsilon}} \omega, x)|^p \rangle dx = \int_Q \langle |u(\omega, x)|^p \rangle dx = \|u\|_{L^p(\Omega \times Q)}^p,$$

where the first and last equality is Fubini's theorem and in the middle, for fixed a.a. $x \in Q$, we use a change of variables $\tau_{-\frac{x}{\varepsilon}} \omega \rightsquigarrow \omega$ and the P -preserving property of this transformation (Assumption 2.1 (ii)).

Since $L^p(\Omega) \overset{a}{\otimes} L^p(Q)$ is dense in $L^p(\Omega \times Q)$, \mathcal{T}_ε extends to a linear isometry from $L^p(\Omega \times Q)$ to $L^p(\Omega \times Q)$. We define a linear isometry $\mathcal{T}_{-\varepsilon} : L^q(\Omega \times Q) \rightarrow L^q(\Omega \times Q)$ analogously as \mathcal{T}_ε , with ε replaced by $-\varepsilon$. Then for any $\varphi \in L^p(\Omega) \overset{a}{\otimes} L^p(Q)$ and $\psi \in L^q(\Omega) \overset{a}{\otimes} L^q(Q)$ we have (thanks to the measure preserving property of τ):

$$\begin{aligned} \left\langle \int_Q (\mathcal{T}_\varepsilon \varphi) \psi dx \right\rangle &= \int_Q \langle \varphi(\tau_{-\frac{x}{\varepsilon}} \omega, x) \psi(\omega, x) \rangle dx \\ &= \int_Q \langle \varphi(\omega, x) \psi(\tau_{\frac{x}{\varepsilon}} \omega, x) \rangle dx = \left\langle \int_Q \varphi(\mathcal{T}_{-\varepsilon} \psi) dx \right\rangle. \end{aligned}$$

Since $L^p(\Omega) \overset{a}{\otimes} L^p(Q)$ and $L^q(\Omega) \overset{a}{\otimes} L^q(Q)$ are dense in $L^p(\Omega \times Q)$ and $L^q(\Omega \times Q)$, respectively, we conclude that $\mathcal{T}_\varepsilon^* = \mathcal{T}_{-\varepsilon}$. Since $\mathcal{T}_\varepsilon^*$ is an isometry, it follows that \mathcal{T}_ε is surjective (see [11, Theorem 2.20]). Analogously, $\mathcal{T}_\varepsilon^*$ is also surjective. \square

Proof of Proposition 3.5. We first note that V is a Carathéodory integrand in the sense of Remark A.2 (if necessary we tacitly redefine it by $V(\omega, x, \cdot) = 0$ for (ω, x) in a set of measure 0) and therefore it follows that V is a normal integrand (see Appendix A). For fixed $\varepsilon > 0$, the mapping $(\omega, x) \mapsto (\tau_{\frac{x}{\varepsilon}} \omega, x)$ is $(\mathcal{F} \otimes \mathcal{L}(Q), \mathcal{F} \otimes \mathcal{L}(Q))$ -measurable and therefore $(\omega, x, F) \mapsto V(\tau_{\frac{x}{\varepsilon}} \omega, x, F)$ defines as well a Carathéodory and thus normal integrand. Hence, with the help of the growth condition, all the integrals in the statement of the proposition are well-defined.

Proof of (i): We first consider the case $u \in L^p(\Omega) \overset{a}{\otimes} L^p(Q)^m$. By Fubini's theorem, the measure preserving property of τ , and by the transformation $\omega \mapsto \tau_{-\frac{x}{\varepsilon}} \omega$, we have

$$\begin{aligned} \left\langle \int_Q V(\tau_{\frac{x}{\varepsilon}} \omega, x, u(\omega, x)) dx \right\rangle &= \int_Q \langle V(\tau_{\frac{x}{\varepsilon}} \omega, x, u(\omega, x)) \rangle dx \\ &= \int_Q \langle V(\omega, x, u(\tau_{-\frac{x}{\varepsilon}} \omega, x)) \rangle dx. \end{aligned}$$

Since $u \in L^p(\Omega) \overset{a}{\otimes} L^p(Q)$, we have $u(\tau_{-\frac{x}{\varepsilon}} \omega, x) = \mathcal{T}_\varepsilon u(\omega, x)$, and thus (12) follows. The general case follows by an approximation argument. Indeed, for any $u \in L^p(\Omega \times Q)^m$ we can find a sequence $u_k \in L^p(\Omega) \overset{a}{\otimes} L^p(Q)^m$ such that $u_k \rightarrow u$ strongly in $L^p(\Omega \times Q)^m$, and by passing to a subsequence (not relabeled) we may additionally assume that $u_k \rightarrow u$ pointwise a.e. in $\Omega \times Q$. By continuity of V in its last variable, we thus have $V(\tau_{\frac{x}{\varepsilon}} \omega, x, u_k(\omega, x)) \rightarrow V(\tau_{\frac{x}{\varepsilon}} \omega, x, u(\omega, x))$ for a.e. $(\omega, x) \in \Omega \times Q$. Since

$|V(\tau_\varepsilon \omega, x, u_k(\omega, x))| \leq c(1 + |u_k(\omega, x)|^p)$ a.e. in $\Omega \times Q$, the dominated convergence theorem ([8, Theorem 2.8.8]) implies that

$$\lim_{k \rightarrow \infty} \left\langle \int_Q V(\tau_\varepsilon \omega, x, u_k(\omega, x)) dx \right\rangle = \left\langle \int_Q V(\tau_\varepsilon \omega, x, u(\omega, x)) dx \right\rangle.$$

In the same way we conclude that

$$\lim_{k \rightarrow \infty} \left\langle \int_Q V(\omega, x, \mathcal{T}_\varepsilon u_k(\omega, x)) dx \right\rangle = \left\langle \int_Q V(\omega, x, \mathcal{T}_\varepsilon u(\omega, x)) dx \right\rangle.$$

Since the integrals on the left-hand sides are the same, (12) follows.

Proof of (ii): We get $\left\langle \int_Q V(\tau_\varepsilon \omega, x, u_\varepsilon(\omega, x)) dx \right\rangle = \left\langle \int_Q V(\omega, x, \mathcal{T}_\varepsilon u_\varepsilon(\omega, x)) dx \right\rangle$ by part (i). Since by assumption $\mathcal{T}_\varepsilon u_\varepsilon \rightarrow u$ strongly in $L^p(\Omega \times Q)^m$, using the growth conditions of V and the dominated convergence theorem, it follows, similarly to part (i), that $\lim_{\varepsilon \rightarrow 0} \left\langle \int_Q V(\omega, x, \mathcal{T}_\varepsilon u_\varepsilon(\omega, x)) dx \right\rangle = \left\langle \int_Q V(\omega, x, u(\omega, x)) dx \right\rangle$.

Proof of (iii): The functional $L^p(\Omega \times Q)^m \ni u \mapsto \left\langle \int_Q V(\omega, x, u(\omega, x)) dx \right\rangle$ is convex and lower semi-continuous, therefore it is weakly lower semi-continuous (see [11, Corollary 3.9]). Combining this fact with the transformation formula from (i) and the weak convergence $\mathcal{T}_\varepsilon u_\varepsilon \rightarrow u$ (by assumption), the claim follows. \square

Before stating the proof of Proposition 3.7, we present some auxiliary lemmas.

Lemma 3.11. *Let $p \in (1, \infty)$ and $q = \frac{p}{p-1}$.*

(i) *If $\varphi \in \{D^* \psi : \psi \in W^{1,q}(\Omega)^d\}^\perp$, then $\varphi \in L_{\text{inv}}^p(\Omega)$.*

(ii) *If $\varphi \in \{\psi \in W^{1,q}(\Omega)^d : D^* \psi = 0\}^\perp$, then $\varphi \in L_{\text{pot}}^p(\Omega)$.*

Proof. *Proof of (i).* First, we note that

$$\varphi \in L_{\text{inv}}^p(\Omega) \iff U_{he_i} \varphi = \varphi \quad \text{for all } h \in \mathbb{R}, i = 1, \dots, d.$$

We consider $\varphi \in \{D^* \psi : \psi \in W^{1,q}(\Omega)^d\}^\perp$ and we show that $\varphi \in L_{\text{inv}}^p(\Omega)$ using the above equivalence. Let $\psi \in W^{1,q}(\Omega)$ and $i \in \{1, \dots, d\}$. Classical semigroup theory arguments (cf. [18, Section 7.4.1]) imply that $\frac{d}{dh} U_{he_i} \psi = D_i U_{he_i} \psi = U_{he_i} D_i \psi = -U_{he_i} D_i^* \psi$, where the last inequality follows by (4). Therefore, an integration over $(0, -h)$ yields $U_{-he_i} \psi - \psi = \int_0^h U_{-te_i} D_i^* \psi dt$ and thus

$$\langle (U_{he_i} \varphi - \varphi) \psi \rangle = \langle \varphi (U_{-he_i} \psi - \psi) \rangle = \langle \varphi \int_0^h U_{-te_i} D_i^* \psi dt \rangle = \int_0^h \langle \varphi D_i^* (U_{-te_i} \psi) \rangle dt.$$

Since $U_{-te_i} \psi \in W^{1,q}(\Omega)$ for any $t \in [0, h]$ and $D^*(U_{-te_i} \psi e_i) = D_i^*(U_{-te_i} \psi)$, we obtain $\langle \varphi D_i^* (U_{-te_i} \psi) \rangle = 0$ and thus $U_{he_i} \varphi = \varphi$.

Proof of (ii). In view of $L_{\text{pot}}^p(\Omega) = \ker(D^*)^\perp$ (see (16)), it is sufficient to prove that the set $\{\varphi \in W^{1,q}(\Omega)^d : D^* \varphi = 0\}$ is dense in $\ker(D^*)$. This follows by an approximation argument as in [25, Section 7.2]. Let $\varphi \in \ker(D^*)$ and we define for $t > 0$

$$\varphi^t(\omega) = \int_{\mathbb{R}^d} p_t(y) \varphi(\tau_y \omega) dy, \quad \text{where } p_t(y) = \frac{1}{(4\pi t)^{\frac{d}{2}}} e^{-\frac{|y|^2}{4t}}.$$

Then the claimed density follows, since $\varphi^t \in W^{1,q}(\Omega)^d$, $D^* \varphi^t = 0$ for any $t > 0$ and $\varphi^t \rightarrow \varphi$ strongly in $L^q(\Omega)^d$ as $t \rightarrow 0$. The last statement can be seen as

follows. By the continuity property of U_y , for any $\varepsilon > 0$ there exists $\delta > 0$ such that $\langle |\varphi(\tau_y\omega) - \varphi(\omega)|^q \rangle \leq \varepsilon$ for any $y \in B_\delta(0)$. It follows that

$$\begin{aligned} \langle |\varphi^t - \varphi|^q \rangle &= \left\langle \left| \int_{\mathbb{R}^d} p_t(y) (\varphi(\tau_y\omega) - \varphi(\omega)) dy \right|^q \right\rangle \\ &\leq \int_{\mathbb{R}^d} p_t(y) \langle |\varphi(\tau_y\omega) - \varphi(\omega)|^q \rangle dy \\ &= \int_{B_\delta} p_t(y) \langle |\varphi(\tau_y\omega) - \varphi(\omega)|^q \rangle dy + \int_{\mathbb{R}^d \setminus B_\delta} p_t(y) \langle |\varphi(\tau_y\omega) - \varphi(\omega)|^q \rangle dy. \end{aligned}$$

The first term on the right-hand side of the above inequality is bounded by ε as well as the second term for sufficiently small $t > 0$. \square

Lemma 3.12. *Let $p \in (1, \infty)$ and $Q \subset \mathbb{R}^d$ be open. Let $u_\varepsilon \in L^p(\Omega) \otimes W^{1,p}(Q)$ be such that $u_\varepsilon \xrightarrow{2} u$ in $L^p(\Omega \times Q)$ and $\varepsilon \nabla u_\varepsilon \xrightarrow{2} 0$ in $L^p(\Omega \times Q)^d$. Then $u \in L^p_{\text{inv}}(\Omega) \otimes L^p(Q)$.*

Proof. Consider a sequence $v_\varepsilon = \varepsilon \mathcal{T}_\varepsilon^*(\varphi\eta)$ such that $\varphi \in W^{1,q}(\Omega)$ and $\eta \in C_c^\infty(Q)$. Note that $\mathcal{T}_\varepsilon v_\varepsilon = \varepsilon \varphi \eta$ and we have, for $i = 1, \dots, d$ and as $\varepsilon \rightarrow 0$,

$$\left\langle \int_Q \partial_i u_\varepsilon v_\varepsilon dx \right\rangle = \left\langle \int_Q (\mathcal{T}_\varepsilon \partial_i u_\varepsilon) (\mathcal{T}_\varepsilon v_\varepsilon) dx \right\rangle = \left\langle \int_Q (\mathcal{T}_\varepsilon \partial_i u_\varepsilon) \varepsilon \varphi \eta dx \right\rangle \rightarrow 0.$$

Moreover, it holds that $\partial_i v_\varepsilon = \mathcal{T}_\varepsilon^*(D_i \varphi \eta + \varepsilon \varphi \partial_i \eta)$ and therefore

$$\begin{aligned} \left\langle \int_Q \partial_i u_\varepsilon v_\varepsilon dx \right\rangle &= - \left\langle \int_Q u_\varepsilon \partial_i v_\varepsilon dx \right\rangle = - \left\langle \int_Q u_\varepsilon \mathcal{T}_\varepsilon^*(D_i \varphi \eta + \varepsilon \varphi \partial_i \eta) dx \right\rangle \\ &= - \left\langle \int_Q (\mathcal{T}_\varepsilon u_\varepsilon) D_i \varphi \eta + \varepsilon (\mathcal{T}_\varepsilon u_\varepsilon) \varphi \partial_i \eta dx \right\rangle. \end{aligned}$$

The last expression converges to $- \left\langle \int_Q u D_i \varphi \eta dx \right\rangle$ as $\varepsilon \rightarrow 0$. As a result of this, $\langle u(x) D_i \varphi \rangle = 0$ for almost every $x \in Q$ and therefore $u \in L^p_{\text{inv}}(\Omega) \otimes L^p(Q)$ by Lemma 3.11 (i). \square

Lemma 3.13. *Let $p \in (1, \infty)$ and $Q \subset \mathbb{R}^d$ be open. Let u_ε be a bounded sequence in $L^p(\Omega) \otimes W^{1,p}(Q)$. Then there exists $u \in L^p_{\text{inv}}(\Omega) \otimes W^{1,p}(Q)$ such that (up to a subsequence)*

$$u_\varepsilon \xrightarrow{2} u \text{ in } L^p(\Omega \times Q), \quad P_{\text{inv}} u_\varepsilon \xrightarrow{2} u \text{ in } L^p(\Omega \times Q), \quad P_{\text{inv}} \nabla u_\varepsilon \xrightarrow{2} \nabla u \text{ in } L^p(\Omega \times Q)^d.$$

In particular, it holds that $P_{\text{inv}} u_\varepsilon \rightharpoonup u$ weakly in $L^p_{\text{inv}}(\Omega) \otimes W^{1,p}(Q)$.

Proof. Step 1. Proof of the identity $P_{\text{inv}} \circ \mathcal{T}_\varepsilon = \mathcal{T}_\varepsilon \circ P_{\text{inv}} = P_{\text{inv}}$. The second identity holds by definition of P_{inv} . To show that $P_{\text{inv}} \circ \mathcal{T}_\varepsilon = P_{\text{inv}}$, we consider $v \in L^p(\Omega \times Q)$, $\varphi \in L^q(\Omega)$ and $\eta \in L^q(Q)$. We have

$$\begin{aligned} \left\langle \int_Q (P_{\text{inv}} \mathcal{T}_\varepsilon v) (\varphi \eta) dx \right\rangle &= \left\langle \int_Q (\mathcal{T}_\varepsilon v) P_{\text{inv}}^* (\varphi \eta) dx \right\rangle = \left\langle \int_Q v P_{\text{inv}}^* (\varphi \eta) dx \right\rangle \\ &= \left\langle \int_Q (P_{\text{inv}} v) (\varphi \eta) dx \right\rangle, \quad (17) \end{aligned}$$

where we use the fact that $\mathcal{T}_\varepsilon^* P_{\text{inv}}^* = P_{\text{inv}}^*$ since $P_{\text{inv}}^* = P_{\text{inv}} : L^q(\Omega) \rightarrow L^q_{\text{inv}}(\Omega)$. The last equality follows by a density argument and the fact that for $\varphi \in L^2(\Omega)$ it holds $P_{\text{inv}} \varphi = P_{\text{inv}}^* \varphi$, which is obtained by $\langle P_{\text{inv}}^* \varphi, \psi \rangle = \langle \varphi, P_{\text{inv}} \psi \rangle = \langle \varphi, \psi \rangle$ for

all $\psi \in L^2_{\text{inv}}(\Omega)$. Finally, $P_{\text{inv}} \circ \mathcal{T}_\varepsilon = P_{\text{inv}}$ follows by (17) and an approximation argument since $L^q(\Omega) \overset{a}{\otimes} L^q(Q)$ is dense in $L^q(\Omega \times Q)$.

Step 2. Convergence of $P_{\text{inv}}u_\varepsilon$. Since u_ε is bounded in $L^p(\Omega) \otimes W^{1,p}(Q)$, we may extract a (not relabeled) subsequence such that $u_\varepsilon \rightharpoonup v$ weakly in $L^p(\Omega) \otimes W^{1,p}(Q)$. P_{inv} is a linear and bounded operator and thus we conclude that

$$P_{\text{inv}}u_\varepsilon \rightharpoonup P_{\text{inv}}v \text{ weakly in } L^p(\Omega \times Q), \quad P_{\text{inv}}\nabla u_\varepsilon \rightharpoonup P_{\text{inv}}\nabla v \text{ weakly in } L^p(\Omega \times Q)^d.$$

Moreover, since P_{inv} commutes with ∇ , it follows that $P_{\text{inv}}u_\varepsilon \rightharpoonup P_{\text{inv}}v$ weakly in $L^p(\Omega) \otimes W^{1,p}(Q)$. Furthermore, by $\mathcal{T}_\varepsilon \circ P_{\text{inv}} = P_{\text{inv}}$, we have

$$P_{\text{inv}}u_\varepsilon \overset{2}{\rightharpoonup} P_{\text{inv}}v \text{ in } L^p(\Omega \times Q), \quad P_{\text{inv}}\nabla u_\varepsilon \overset{2}{\rightharpoonup} P_{\text{inv}}\nabla v = \nabla P_{\text{inv}}v \text{ in } L^p(\Omega \times Q)^d.$$

Step 3. Convergence of u_ε . Since u_ε is bounded, using Lemma 3.4 (ii) and Lemma 3.12 there exists $u \in L^p_{\text{inv}}(\Omega) \otimes L^p(Q)$ such that $u_\varepsilon \overset{2}{\rightharpoonup} u$ in $L^p(\Omega \times Q)$. Also, P_{inv} is a linear and bounded operator which, together with $P_{\text{inv}} \circ \mathcal{T}_\varepsilon = P_{\text{inv}}$ from Step 1, implies that $P_{\text{inv}}u_\varepsilon \rightharpoonup P_{\text{inv}}u = u$. Using this, we conclude that $u = P_{\text{inv}}v$. \square

Proof of Proposition 3.7. Lemma 3.13 implies that $u_\varepsilon \overset{2}{\rightharpoonup} u$ in $L^p(\Omega \times Q)$ (up to a subsequence), where $u \in L^p_{\text{inv}}(\Omega) \otimes W^{1,p}(Q)$. Moreover, it follows that there exists $v \in L^p(\Omega \times Q)^d$ such that $\nabla u_\varepsilon \overset{2}{\rightharpoonup} v$ in $L^p(\Omega \times Q)^d$ (up to another subsequence). We show that $\chi := v - \nabla u \in L^p_{\text{pot}}(\Omega) \otimes L^p(Q)$.

Let $\varphi \in W^{1,q}(\Omega)^d$ with $D^*\varphi = 0$ and $\eta \in C_c^\infty(Q)$. We have, as $\varepsilon \rightarrow 0$,

$$\left\langle \int_Q \nabla u_\varepsilon \cdot \mathcal{T}_\varepsilon^*(\varphi\eta) dx \right\rangle = \left\langle \int_Q \mathcal{T}_\varepsilon \nabla u_\varepsilon \cdot \varphi\eta dx \right\rangle \rightarrow \left\langle \int_Q v \cdot \varphi\eta dx \right\rangle. \quad (18)$$

On the other hand,

$$\begin{aligned} \left\langle \int_Q \nabla u_\varepsilon \cdot \mathcal{T}_\varepsilon^*(\varphi\eta) dx \right\rangle &= - \left\langle \int_Q u_\varepsilon \sum_{i=1}^d \mathcal{T}_\varepsilon^* \left(\frac{1}{\varepsilon} \eta D_i \varphi_i + \varphi_i \partial_i \eta \right) dx \right\rangle \\ &= \frac{1}{\varepsilon} \left\langle \int_Q (\mathcal{T}_\varepsilon u_\varepsilon)(\eta D^* \varphi) dx \right\rangle - \left\langle \int_Q (\mathcal{T}_\varepsilon u_\varepsilon) \sum_{i=1}^d \varphi_i \partial_i \eta dx \right\rangle. \end{aligned} \quad (19)$$

Above, the first term on the right-hand side vanishes by assumption and the second converges to $\left\langle \int_Q \nabla u \cdot \varphi\eta \right\rangle$ as $\varepsilon \rightarrow 0$. Using (19), (18) and Lemma 3.11 (ii) we complete the proof. \square

Proof of Lemma 3.9. For $\chi \in L^p_{\text{pot}}(\Omega) \otimes L^p(Q)$ and $\delta > 0$, by definition of the space $L^p_{\text{pot}}(\Omega) \otimes L^p(Q)$ and by density of $\text{ran}(D)$ in $L^p_{\text{pot}}(\Omega)$, we find $g_\delta = \sum_{i=1}^{n(\delta)} \varphi_i^\delta \eta_i^\delta$ with $\varphi_i^\delta \in W^{1,p}(\Omega)$ and $\eta_i^\delta \in C_c^\infty(Q)$ such that

$$\|\chi - Dg_\delta\|_{L^p(\Omega \times Q)^d} \leq \delta.$$

Note that we can choose φ_i^δ above so that $\varphi_i^\delta \in L^\theta(\Omega)$. This can be seen by a standard truncation and mollification argument (see [9, Lemma 2.2] for the L^2 -case) that we present here for the convenience of the reader. For a given $\varphi \in W^{1,p}(\Omega)$, by density of $L^\infty(\Omega)$ in $L^p(\Omega)$, we find a sequence $\varphi_k \in L^\infty(\Omega)$ such that $\varphi_k \rightarrow \varphi$ in $L^p(\Omega)$. For a sequence of standard mollifiers $\rho_n \in C_c^\infty(\mathbb{R}^d)$, $\rho_n \geq 0$, we define

$$\varphi_k^n = \int_{\mathbb{R}^d} \rho_n(y) U_y \varphi_k dy, \quad \varphi^n = \int_{\mathbb{R}^d} \rho_n(y) U_y \varphi dy.$$

It holds that $\varphi_k^n \in L^\infty(\Omega) \cap W^{1,p}(\Omega)$, $D_i \varphi_k^n = \int_{\mathbb{R}^d} -\partial_i \rho_n(y) U_y \varphi_k dy$ and $D_i \varphi^n = \int_{\mathbb{R}^d} -\partial_i \rho_n(y) U_y \varphi dy = \int_{\mathbb{R}^d} \rho_n(y) U_y D_i \varphi dy$. Similarly to the proof of Lemma 3.11 (ii), it follows that $D\varphi^n \rightarrow D\varphi$ in $L^p(\Omega)^d$ as $n \rightarrow \infty$. In the following we show that for fixed $n \in \mathbb{N}$, $D_i \varphi_k^n \rightarrow D_i \varphi^n$ in $L^p(\Omega)$ as $k \rightarrow \infty$, which yields the claim (up to extraction of a subsequence $k(n)$). We have, as $k \rightarrow \infty$,

$$\langle |D_i \varphi_k^n - D_i \varphi^n|^p \rangle = \left\langle \left| \int_{\mathbb{R}^d} -\partial_i \rho_n(y) (U_y \varphi_k - U_y \varphi) dy \right|^p \right\rangle \leq c(n) \langle |\varphi_k - \varphi|^p \rangle \rightarrow 0,$$

where in the last inequality we use that $\partial_i \rho_n$ is compactly supported and L^∞ , and Jensen's inequality. This means that in the definition of g_δ above, we can choose $\varphi_i^\delta \in L^\theta(\Omega) \cap W^{1,p}(\Omega)$.

We define $g_{\delta,\varepsilon} = \varepsilon \mathcal{T}_\varepsilon^{-1} g_\delta$ and note that $g_{\delta,\varepsilon} \in L^p(\Omega) \otimes W_0^{1,p}(Q) \cap L^\theta(\Omega \times Q)$ and $\nabla g_{\delta,\varepsilon} = \mathcal{T}_\varepsilon^{-1} Dg_\delta + \mathcal{T}_\varepsilon^{-1} \varepsilon \nabla g_\delta$. As a result of this and with help of the isometry property of $\mathcal{T}_\varepsilon^{-1}$ (which is a consequence of the measure preserving property of τ Assumption 2.1 (ii)), the claim of the lemma follows. \square

4. Proof of Theorem 2.3. Before presenting the main proof, we provide three auxiliary lemmas. Lemma 4.1 provides the reduction of the Λ -convex gradient flows to convex gradient flows. Lemmas 4.3 and 4.4 provide a suitable recovery sequence that is helpful in the treatment of the term $\int_0^T \tilde{\mathcal{E}}_\varepsilon^*(t, -D\mathcal{R}_\varepsilon(\dot{u}_\varepsilon(t))) dt$ in (3) (cf. (20)).

Lemma 4.1 (Convex reduction). *Let $T > 0$ be fixed. Let the assumptions of Theorem 2.3 be satisfied. Let $\tilde{\mathcal{E}}_\varepsilon : [0, T] \times Y \rightarrow \mathbb{R} \cup \{\infty\}$ and $\tilde{\mathcal{E}}_{\text{hom}} : [0, T] \times Y_0 \rightarrow \mathbb{R} \cup \{\infty\}$ be given by*

$$\tilde{\mathcal{E}}_\varepsilon(t, u) = e^{2\Lambda t} \mathcal{E}_\varepsilon(e^{-\Lambda t} u) - \Lambda \mathcal{R}_\varepsilon(u), \quad \tilde{\mathcal{E}}_{\text{hom}}(t, u) = e^{2\Lambda t} \mathcal{E}_{\text{hom}}(e^{-\Lambda t} u) - \Lambda \mathcal{R}_{\text{hom}}(u).$$

Then:

- (i) $\tilde{\mathcal{E}}_\varepsilon$ and $\tilde{\mathcal{E}}_{\text{hom}}$ are convex normal integrands (see Definition A.1).
- (ii) $y \in H^1(0, T; Y)$ satisfies (7) if and only if $u(t) := e^{\Lambda t} y(t)$ satisfies

$$\mathcal{R}_\varepsilon(u(T)) + \int_0^T \tilde{\mathcal{E}}_\varepsilon(t, u(t)) + \tilde{\mathcal{E}}_\varepsilon^*(t, -D\mathcal{R}_\varepsilon(\dot{u}(t))) dt = \mathcal{R}_\varepsilon(u(0)), \quad (20)$$

where $\tilde{\mathcal{E}}_\varepsilon^*(t, \cdot)$ denotes the convex conjugate of $\tilde{\mathcal{E}}_\varepsilon(t, \cdot)$.

- (iii) $y \in H^1(0, T; Y_0)$ satisfies (11) if and only if $u(t) := e^{\Lambda t} y(t)$ satisfies

$$\mathcal{R}_{\text{hom}}(u(T)) + \int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, u(t)) + \tilde{\mathcal{E}}_{\text{hom}}^*(t, -D\mathcal{R}_{\text{hom}}(\dot{u}(t))) dt = \mathcal{R}_{\text{hom}}(u(0)),$$

where $\tilde{\mathcal{E}}_{\text{hom}}^*(t, \cdot)$ denotes the convex conjugate of $\tilde{\mathcal{E}}_{\text{hom}}(t, \cdot)$.

Proof. Proof of (i). For fixed t , convexity of $\tilde{\mathcal{E}}_\varepsilon(t, \cdot)$ follows from Λ -convexity of \mathcal{E}_ε . $\tilde{\mathcal{E}}_\varepsilon(t, \cdot)$ is proper and l.s.c. Indeed, this follows by continuity of \mathcal{R}_ε and by the fact that \mathcal{E}_ε is proper and l.s.c. (cf. Remark 2.2). In the following we show that $\tilde{\mathcal{E}}_\varepsilon$ is $\mathcal{L}(0, T) \otimes \mathcal{B}(Y)$ -measurable that implies the claim for $\tilde{\mathcal{E}}_\varepsilon$. First, we note that $-\Lambda \mathcal{R}_\varepsilon$ is $\mathcal{B}(Y)$ -measurable since it is continuous, therefore it is sufficient to show that the mapping $(t, u) \mapsto e^{2\Lambda t} \mathcal{E}_\varepsilon(e^{-\Lambda t} u)$ is $\mathcal{L}(0, T) \otimes \mathcal{B}(Y)$ -measurable. We note that $\mathcal{E}_\varepsilon(e^{-\Lambda t} u)$ is the composition of the continuous mapping $(t, u) \mapsto e^{-\Lambda t} u$ (thus $(\mathcal{B}(0, T) \otimes \mathcal{B}(Y), \mathcal{B}(Y))$ -measurable) and the l.s.c. functional \mathcal{E}_ε that is, thus, $\mathcal{B}(Y)$ -measurable. As a result of this, it is $\mathcal{B}(0, T) \otimes \mathcal{B}(Y)$ -measurable. Finally,

the expression $e^{2\Lambda t}\mathcal{E}_\varepsilon(e^{-\Lambda t}u)$ is a product of a continuous and a measurable functional and therefore it is $\mathcal{L}(0, T) \otimes \mathcal{B}(Y)$ -measurable. For $\tilde{\mathcal{E}}_{\text{hom}}$, the claim follows analogously.

Proof of (ii). Since \mathcal{R}_ε is quadratic we have $\mathcal{R}_\varepsilon(\tilde{y}) = \frac{1}{2} \langle \text{D}\mathcal{R}_\varepsilon(\tilde{y}), \tilde{y} \rangle_{Y^*, Y}$. Combined with (7), a simple rearrangement yields for all $\tilde{y} \in Y$,

$$\langle \text{D}\mathcal{R}_\varepsilon(\dot{y}(t) + \Lambda y(t)), y(t) - \tilde{y} \rangle_{Y^*, Y} + \mathcal{E}_\varepsilon(y(t)) - \Lambda \mathcal{R}_\varepsilon(y(t)) \leq \mathcal{E}_\varepsilon(\tilde{y}) - \Lambda \mathcal{R}_\varepsilon(\tilde{y}).$$

We multiply the above inequality with $e^{2\Lambda t}$ and use linearity of $\text{D}\mathcal{R}_\varepsilon$ (resp. quadratic structure of \mathcal{R}_ε) to obtain,

$$\begin{aligned} & \langle \text{D}\mathcal{R}_\varepsilon(e^{\Lambda t}\dot{y}(t) + \Lambda e^{\Lambda t}y(t)), e^{\Lambda t}(y(t) - \tilde{y}) \rangle_{Y^*, Y} \\ & + e^{2\Lambda t}\mathcal{E}_\varepsilon(e^{-\Lambda t}e^{\Lambda t}y(t)) - \Lambda \mathcal{R}_\varepsilon(e^{\Lambda t}y(t)) \\ & \leq e^{2\Lambda t}\mathcal{E}_\varepsilon(e^{-\Lambda t}e^{\Lambda t}\tilde{y}) - \Lambda \mathcal{R}_\varepsilon(e^{\Lambda t}\tilde{y}) \quad \text{for all } \tilde{y} \in Y. \end{aligned}$$

With $u(t) = e^{\Lambda t}y(t)$, the definition of $\tilde{\mathcal{E}}_\varepsilon$, and with the test-function $\tilde{y} = e^{-\Lambda t}\hat{y}$, the above inequality reads

$$\langle \text{D}\mathcal{R}_\varepsilon(\dot{u}(t)), u(t) - \hat{y} \rangle_{Y^*, Y} + \tilde{\mathcal{E}}_\varepsilon(t, u(t)) \leq \tilde{\mathcal{E}}_\varepsilon(t, \hat{y}) \quad \text{for all } \hat{y} \in Y,$$

where we used that $\dot{u}(t) = e^{\Lambda t}\dot{y}(t) + \Lambda e^{\Lambda t}y(t)$. Since $\tilde{\mathcal{E}}_\varepsilon(t, \cdot)$ is convex for each t , the Fenchel equivalence implies that u satisfies for a.e. $t \in (0, T)$,

$$\langle \text{D}\mathcal{R}_\varepsilon(\dot{u}(t)), u(t) \rangle_{Y^*, Y} + \tilde{\mathcal{E}}_\varepsilon(t, u(t)) + \tilde{\mathcal{E}}_\varepsilon^*(t, -\text{D}\mathcal{R}_\varepsilon(\dot{u}(t))) = 0. \quad (21)$$

Since $\frac{d}{dt}\mathcal{R}_\varepsilon(u(t)) = \langle \text{D}\mathcal{R}_\varepsilon(u(t)), \dot{u}(t) \rangle_{Y^*, Y} = \langle \text{D}\mathcal{R}_\varepsilon(\dot{u}(t)), u(t) \rangle_{Y^*, Y}$, integration of the above identity over $(0, T)$ yields (20). On the other hand, if (20) holds, then we have

$$\int_0^T \langle \text{D}\mathcal{R}_\varepsilon(\dot{u}(t)), u(t) \rangle_{Y^*, Y} + \tilde{\mathcal{E}}_\varepsilon(t, u(t)) + \tilde{\mathcal{E}}_\varepsilon^*(t, -\text{D}\mathcal{R}_\varepsilon(\dot{u}(t))) dt = 0.$$

The integrand on the left-hand side is nonnegative by the definition of the convex conjugate and therefore it follows that u satisfies (21). This completes the proof.

Proof of (iii). The argument is the same as in part (ii). \square

Remark 4.2 (Extended unfolding). For $p \in (1, \infty)$, the stochastic unfolding operator $\mathcal{T}_\varepsilon : L^p(\Omega \times Q) \rightarrow L^p(\Omega \times Q)$ can be extended to a (not relabeled) linear isometry $\mathcal{T}_\varepsilon : L^p(0, T; L^p(\Omega \times Q)) \rightarrow L^p(0, T; L^p(\Omega \times Q))$. In particular, for functions of the form $u = \eta\varphi \in L^p(0, T; L^p(\Omega \times Q))$ with $\eta \in L^p(0, T)$ and $\varphi \in L^p(\Omega \times Q)$, we define the unfolding by

$$\mathcal{T}_\varepsilon u(t, \cdot) = \eta(t)\mathcal{T}_\varepsilon \varphi(\cdot).$$

By the density of $\{\sum_i \eta_i \varphi_i : \eta_i \in L^p(0, T), \varphi_i \in L^p(\Omega \times Q)\}$ in $L^p(0, T; L^p(\Omega \times Q))$ we may extend the unfolding operator to a uniquely determined isometry on $L^p(0, T; L^p(\Omega \times Q))$. In the following, we use this extension.

Lemma 4.3 (Recovery sequence). *Let $p \in (1, \infty)$, $\theta \in [2, \infty)$ and $Q \subset \mathbb{R}^d$ be open and bounded. Let $w \in L^p(0, T; L_{\text{inv}}^p(\Omega) \otimes W_0^{1,p}(Q)) \cap L^\theta(0, T; L_{\text{inv}}^\theta(\Omega) \otimes L^\theta(Q))$ and $\chi \in L^p(0, T; L_{\text{pot}}^p(\Omega) \otimes L^p(Q))$. Then, there exists $w_\varepsilon \in L^p(0, T; L^p(\Omega) \otimes W_0^{1,p}(Q)) \cap L^\theta(0, T; L^\theta(\Omega \times Q))$ such that, as $\varepsilon \rightarrow 0$,*

$$\begin{aligned} \mathcal{T}_\varepsilon w_\varepsilon &\rightarrow w \quad \text{strongly in } L^\theta(0, T; L^\theta(\Omega \times Q)), \\ \mathcal{T}_\varepsilon \nabla w_\varepsilon &\rightarrow \nabla w + \chi \quad \text{strongly in } L^p(0, T; L^p(\Omega \times Q)^d). \end{aligned}$$

Proof. Since $\chi \in L^p(0, T; L^p_{\text{pot}}(\Omega) \otimes L^p(Q))$, we find a sequence $\psi^k = \sum_{i=1}^k \eta^{k,i} \chi^{k,i}$ with $\eta^{k,i} \in C_c^\infty(0, T)$ and $\chi^{k,i} \in L^p_{\text{pot}}(\Omega) \otimes L^p(Q)$, such that

$$\|\psi^k - \chi\|_{L^p(0, T; L^p(\Omega \times Q)^d)} \rightarrow 0 \quad \text{as } k \rightarrow \infty.$$

In view of Lemma 3.9, for each $\chi^{k,i}$ we find $g_{\delta, \varepsilon}^{k,i} \in (L^p(\Omega) \otimes W_0^{1,p}(Q)) \cap L^\theta(\Omega \times Q)$ such that

$$\|g_{\delta, \varepsilon}^{k,i}\|_{L^\theta(\Omega \times Q)} \leq \varepsilon c_{k,i}(\delta), \quad \limsup_{\varepsilon \rightarrow 0} \|\mathcal{T}_\varepsilon \nabla g_{\delta, \varepsilon}^{k,i} - \chi^{k,i}\|_{L^p(\Omega \times Q)^d} \leq \delta.$$

We define $w_{\delta, \varepsilon}^k = w + \sum_{i=1}^k \eta^{k,i} g_{\delta, \varepsilon}^{k,i}$ and we estimate

$$\begin{aligned} & \|\mathcal{T}_\varepsilon w_{\delta, \varepsilon}^k - w\|_{L^\theta(0, T; L^\theta(\Omega \times Q))} + \|\mathcal{T}_\varepsilon \nabla w_{\delta, \varepsilon}^k - (\nabla w + \chi)\|_{L^p(0, T; L^p(\Omega \times Q)^d)} \\ & \leq \left\| \sum_{i=1}^k \eta^{k,i} g_{\delta, \varepsilon}^{k,i} \right\|_{L^\theta(0, T; L^\theta(\Omega \times Q))} + \left\| \sum_{i=1}^k \eta^{k,i} (\mathcal{T}_\varepsilon \nabla g_{\delta, \varepsilon}^{k,i} - \chi^{k,i}) \right\|_{L^p(0, T; L^p(\Omega \times Q)^d)} \\ & \quad + \|\psi^k - \chi\|_{L^p(0, T; L^p(\Omega \times Q)^d)} \\ & \leq \varepsilon \sum_{i=1}^k c_{k,i}(\delta) + \sum_{i=1}^k c_{k,i} \left\| \mathcal{T}_\varepsilon \nabla g_{\delta, \varepsilon}^{k,i} - \chi^{k,i} \right\|_{L^p(\Omega \times Q)^d} + \|\psi^k - \chi\|_{L^p(0, T; L^p(\Omega \times Q)^d)}. \end{aligned}$$

Letting first $\varepsilon \rightarrow 0$, secondly $\delta \rightarrow 0$, and finally $k \rightarrow \infty$, the right-hand side above vanishes. As a result of this, we can extract diagonal sequences $k(\varepsilon)$ and $\delta(\varepsilon)$ such that $w_\varepsilon := w_{\delta(\varepsilon), \varepsilon}^{k(\varepsilon)}$ satisfies the claim of the lemma. \square

Lemma 4.4 (Measurable selection). *Let the assumptions of Lemma 4.1 be satisfied. Let $\xi \in L^2(0, T; Y_0^*)$. There exists $w \in L^p(0, T; L^p_{\text{inv}}(\Omega) \otimes W_0^{1,p}(Q)) \cap L^\theta(0, T; L^\theta_{\text{inv}}(\Omega) \otimes L^\theta(Q))$ such that*

$$\int_0^T \tilde{\mathcal{E}}_{\text{hom}}^*(t, \xi(t)) dt = \int_0^T \langle \xi(t), w(t) \rangle_{Y_0^*, Y_0} dt - \int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, w(t)) dt.$$

Moreover, there exists $\chi \in L^p(0, T; L^p_{\text{pot}}(\Omega) \otimes L^p(Q))$ such that

$$\begin{aligned} & \int_0^T \inf_{\chi \in L^p_{\text{pot}}(\Omega) \otimes L^p(Q)} \left\langle \int_Q e^{2\Lambda t} V(\omega, x, e^{-\Lambda t} \nabla w(t) + \chi) dx \right\rangle dt \\ & = \int_0^T \left\langle \int_Q e^{2\Lambda t} V(\omega, x, e^{-\Lambda t} \nabla w(t) + \chi(t)) dx \right\rangle dt. \end{aligned} \quad (22)$$

Proof. First we note that $\tilde{\mathcal{E}}_{\text{hom}}$ is a convex normal integrand by Lemma 4.1 (i) and $\int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, 0) dt < \infty$. Therefore, Proposition A.4 in Appendix A implies that

$$\begin{aligned} & \int_0^T \tilde{\mathcal{E}}_{\text{hom}}^*(t, \xi(t)) dt \\ & = \sup_{w \in L^2(0, T; Y_0)} \left(\int_0^T \langle \xi(t), w(t) \rangle_{Y_0^*, Y_0} dt - \int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, w(t)) dt \right). \end{aligned} \quad (23)$$

The supremum on the right-hand side is attained by some $w \in L^2(0, T; Y_0)$. Indeed, the right-hand side of (23) equals

$$- \inf_{w \in L^2(0, T; Y_0)} \left(\int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, w(t)) dt - \int_0^T \langle \xi(t), w(t) \rangle_{Y_0^*, Y_0} dt \right). \quad (24)$$

For a minimizing sequence $w_k \in L^2(0, T; Y_0)$ of this problem the growth conditions of V, f and \mathcal{R}_{hom} imply that

$$\|w_k\|_{L^p(0, T; L^p_{\text{inv}}(\Omega) \otimes W^{1, p}(Q))} + \|w_k\|_{L^\theta(0, T; L^\theta_{\text{inv}}(\Omega) \otimes L^\theta(Q))} \leq c(T).$$

In this respect, we may extract a weakly convergent subsequence in the corresponding spaces in order to apply the direct method of the calculus of variations and conclude that the minimum in (24) is attained. We remark that we use that the functional in (24) is convex and therefore l.s.c. As a result of the above, we also have $\int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, w(t)) dt < \infty$, which implies that $w \in L^p(0, T; L^p_{\text{inv}}(\Omega) \otimes W_0^{1, p}(Q)) \cap L^\theta(0, T; L^\theta_{\text{inv}}(\Omega) \otimes L^\theta(Q))$.

To show (22), we define an integrand $\mathcal{I} : [0, T] \times (L^p_{\text{pot}}(\Omega) \otimes L^p(Q)) \rightarrow \mathbb{R} \cup \{\infty\}$ by $\mathcal{I}(t, \chi) = e^{2\Lambda t} \left\langle \int_Q V(\omega, x, e^{-\Lambda t} \nabla w(t)(\omega, x) + \chi(\omega, x)) dx \right\rangle$. We remark that \mathcal{I} is finite everywhere (up to considering a suitable representative of ∇w) and for all $t \in [0, T]$, $\mathcal{I}(t, \cdot)$ is convex and l.s.c. (using the growth conditions of V), in fact, $\mathcal{I}(t, \cdot)$ is continuous. Moreover, for each fixed $\chi \in L^p_{\text{pot}}(\Omega) \otimes L^p(Q)$, $\mathcal{I}(\cdot, \chi)$ is $\mathcal{L}(0, T)$ -measurable. Indeed, this follows by the observation that $\mathcal{I}(\cdot, \chi)$ is a composition of the mappings $g_1 : [0, T] \rightarrow [0, T] \times L^p(\Omega \times Q)^d$, $g_1(t) = (t, e^{-\Lambda t} \nabla w(t) + \chi)$, and $g_2 : [0, T] \times L^p(\Omega \times Q)^d \rightarrow \mathbb{R}$, $g_2(t, \varphi) = e^{2\Lambda t} \left\langle \int_Q V(\omega, x, \varphi(\omega, x)) dx \right\rangle$. g_1 is $(\mathcal{L}(0, T), \mathcal{L}(0, T) \otimes \mathcal{B}(L^p(\Omega \times Q)^d))$ -measurable and g_2 is a Carathéodory integrand and therefore $(\mathcal{L}(0, T) \otimes \mathcal{B}(L^p(\Omega \times Q)^d))$ -measurable. The above statements imply that \mathcal{I} is a convex Carathéodory integrand, thus a normal convex integrand (see Appendix A). As a result of this, Proposition A.4 (and in particular Remark A.5) in Appendix A implies that

$$\int_0^T \inf_{\chi \in L^p_{\text{pot}}(\Omega) \otimes L^p(Q)} \mathcal{I}(t, \chi) dt = \inf_{\chi \in L^p(0, T; L^p_{\text{pot}}(\Omega) \otimes L^p(Q))} \int_0^T \mathcal{I}(t, \chi(t)) dt.$$

The infimum on the right-hand side is attained at some $\chi \in L^p(0, T; L^p_{\text{pot}}(\Omega) \otimes L^p(Q))$, which is obtained similarly to the problem (24) using the direct method of the calculus of variations. This concludes the proof. \square

Proof of Theorem 2.3. Step 1. Compactness. The apriori estimate (9) and the boundedness of $\mathcal{E}_\varepsilon(y_\varepsilon^0)$ yield, for all $t \in [0, T]$,

$$\|y_\varepsilon(t)\|_{L^p(\Omega) \otimes W^{1, p}(Q)}^p + \|y_\varepsilon(t)\|_{L^\theta(\Omega \times Q)}^\theta \leq c. \quad (25)$$

Also, by the isometry property of \mathcal{T}_ε and since $\theta \geq 2$, the above implies that $\|\mathcal{T}_\varepsilon y_\varepsilon(t)\|_Y^\theta \leq c$. We remark that $\mathcal{T}_\varepsilon y_\varepsilon \in H^1(0, T; Y)$ since (\cdot) and \mathcal{T}_ε commute, i.e., $\frac{d}{dt} (\mathcal{T}_\varepsilon y_\varepsilon) = \mathcal{T}_\varepsilon \dot{y}_\varepsilon$, where on the left-hand side $\mathcal{T}_\varepsilon y_\varepsilon$ is pointwise defined as $\mathcal{T}_\varepsilon y_\varepsilon(t)$ and on the right-hand side \mathcal{T}_ε is the extension defined on $L^2(0, T; Y)$. As a result of this and using the isometry property of \mathcal{T}_ε , the apriori estimate (8) implies that

$$\|\mathcal{T}_\varepsilon y_\varepsilon\|_{H^1(0, T; Y)}^2 \leq c, \quad \|\mathcal{T}_\varepsilon y_\varepsilon(t) - \mathcal{T}_\varepsilon y_\varepsilon(s)\|_Y^2 \leq c|t - s| \quad \text{for all } s, t \in [0, T].$$

We extract a (not relabeled) subsequence and $y \in H^1(0, T; Y)$ such that $\mathcal{T}_\varepsilon y_\varepsilon \rightharpoonup y$ weakly in $H^1(0, T; Y)$, and this implies that $\mathcal{T}_\varepsilon \dot{y}_\varepsilon \rightharpoonup \dot{y}$ weakly in $L^2(0, T; Y)$. We apply the Arzelà-Ascoli theorem to the sequence $\mathcal{T}_\varepsilon y_\varepsilon$ to obtain that (up to another subsequence) for all $t \in [0, T]$,

$$\mathcal{T}_\varepsilon y_\varepsilon(t) \rightharpoonup y(t) \quad \text{weakly in } Y. \quad (26)$$

Using (25) and Proposition 3.7, we conclude that $y(t) \in (L_{\text{inv}}^p(\Omega) \otimes W_0^{1,p}(Q)) \cap (L_{\text{inv}}^\theta(\Omega) \otimes L^\theta(Q))$ and

$$\mathcal{T}_\varepsilon y_\varepsilon(t) \rightharpoonup y(t) \quad \text{weakly in } L^\theta(\Omega \times Q) \text{ and in } L^p(\Omega \times Q). \quad (27)$$

In particular, here we also used Remark 3.8 to conclude that $y(t)$ has 0 boundary values. These facts also imply that $y \in H^1(0, T; Y_0)$. Moreover, for each $t \in [0, T]$ we find $\chi(t) \in L_{\text{pot}}^p(\Omega) \otimes L^p(Q)$ and a subsequence $\varepsilon(t)$ such that $\mathcal{T}_{\varepsilon(t)} \nabla y_{\varepsilon(t)}(t) \rightharpoonup \nabla y(t) + \chi(t)$ weakly in $L^p(\Omega \times Q)^d$. This implies that $P_{\text{inv}} \nabla y_\varepsilon(t) \rightharpoonup \nabla y(t)$ weakly in $L^p(\Omega \times Q)^d$ for the whole (sub)sequence ε . Note that the assumption on the initial data implies that $\mathcal{T}_\varepsilon y_\varepsilon(0) \rightarrow y^0$ strongly in Y and hence we have $y(0) = y^0$.

In the following step, using Lemma 4.1, we restate (7) as a convex problem. For this reason, we define the new variables $u_\varepsilon(t) = e^{\Lambda t} y_\varepsilon(t)$ and $u(t) = e^{\Lambda t} y(t)$. We remark that since $y(t)$ is in the space of shift invariant functions, $u(t)$ also inherits this property, i.e. $u(t) \in (L_{\text{inv}}^p(\Omega) \otimes W_0^{1,p}(Q)) \cap (L_{\text{inv}}^\theta(\Omega) \otimes L^\theta(Q))$. Note that $\dot{u}_\varepsilon(t) = \Lambda e^{\Lambda t} y_\varepsilon(t) + e^{\Lambda t} \dot{y}_\varepsilon(t)$ and analogously for \dot{u} . The above convergence statements result in

$$\begin{aligned} \mathcal{T}_\varepsilon u_\varepsilon &\rightharpoonup u \quad \text{weakly in } H^1(0, T; Y), \\ \mathcal{T}_\varepsilon u_\varepsilon(t) &\rightharpoonup u(t) \quad \text{weakly in } L^\theta(\Omega \times Q) \text{ and } L^p(\Omega \times Q), \quad \text{for all } t \in [0, T]. \end{aligned} \quad (28)$$

Step 2. Reduction to a convex problem. In view of Lemma 4.1 (ii), we have

$$\mathcal{R}_\varepsilon(u_\varepsilon(T)) + \int_0^T \tilde{\mathcal{E}}_\varepsilon(t, u_\varepsilon(t)) + \tilde{\mathcal{E}}_\varepsilon^*(t, -D\mathcal{R}_\varepsilon(\dot{u}_\varepsilon(t))) dt = \mathcal{R}_\varepsilon(u_\varepsilon(0)). \quad (29)$$

Step 3. Passage to the limit $\varepsilon \rightarrow 0$ in (29). Note that $u_\varepsilon(0) = y_\varepsilon^0 \xrightarrow{2} y^0 = u(0)$ in Y and therefore using Proposition 3.5 (ii), for the right-hand side of (29), we have

$$\lim_{\varepsilon \rightarrow 0} \mathcal{R}_\varepsilon(u_\varepsilon(0)) = \mathcal{R}_{\text{hom}}(u(0)). \quad (30)$$

The first term on the left-hand side is treated similarly, using Proposition 3.5 (iii) and (28), we have

$$\liminf_{\varepsilon \rightarrow 0} \mathcal{R}_\varepsilon(u_\varepsilon(T)) \geq \mathcal{R}_{\text{hom}}(u(T)). \quad (31)$$

We treat the second term on the left-hand side of (29) as follows. By Fatou's lemma we have

$$\begin{aligned} &\liminf_{\varepsilon \rightarrow 0} \int_0^T \tilde{\mathcal{E}}_\varepsilon(t, u_\varepsilon(t)) dt \\ &\geq \int_0^T \liminf_{\varepsilon \rightarrow 0} \left\langle \int_Q e^{2\Lambda t} V(\tau_{\frac{x}{\varepsilon}} \omega, x, e^{-\Lambda t} \nabla u_\varepsilon(t)) dx \right\rangle dt \\ &\quad + \int_0^T \liminf_{\varepsilon \rightarrow 0} \left\langle \int_Q e^{2\Lambda t} f(\tau_{\frac{x}{\varepsilon}} \omega, x, e^{-\Lambda t} u_\varepsilon(t)) - \frac{\Lambda}{2} r(\tau_{\frac{x}{\varepsilon}} \omega, x) |u_\varepsilon(t)|^2 dx \right\rangle dt. \end{aligned}$$

For fixed t , the \liminf in the first term is a limit for a subsequence $\varepsilon(t)$ and as in Step 1 we find $\chi(t) \in L_{\text{pot}}^p(\Omega) \otimes L^p(Q)$ such that, up to another (not relabeled) subsequence, it holds $\nabla u_{\varepsilon(t)}(t) \xrightarrow{2} \nabla u(t) + e^{\Lambda t} \chi(t)$ in $L^p(\Omega \times Q)^d$. Also, we notice that $e^{2\Lambda t} V(\omega, x, e^{-\Lambda t} \cdot)$ is convex and has p -growth properties and therefore

Proposition 3.5 (iii) implies that

$$\begin{aligned} & \liminf_{\varepsilon \rightarrow 0} \left\langle \int_Q e^{2\Lambda t} V(\tau_{\varepsilon} \omega, x, e^{-\Lambda t} \nabla u_{\varepsilon}(t)) dx \right\rangle \\ & \geq \left\langle \int_Q e^{2\Lambda t} V(\omega, x, e^{-\Lambda t} \nabla u(t) + \chi(t)) dx \right\rangle \\ & \geq \inf_{\chi \in L^p_{\text{pot}}(\Omega) \otimes L^p(Q)} \left\langle \int_Q e^{2\Lambda t} V(\omega, x, e^{-\Lambda t} \nabla u(t) + \chi) dx \right\rangle. \end{aligned}$$

On the other hand, we remark that the integrand $e^{2\Lambda t} f(\omega, x, e^{-\Lambda t} \cdot) - \frac{\Lambda}{2} r(\omega, x) |\cdot|^2$ is convex and satisfies θ -growth conditions. As a result of this and by (28), Proposition 3.5 (iii) yields

$$\begin{aligned} & \liminf_{\varepsilon \rightarrow 0} \left\langle \int_Q e^{2\Lambda t} f(\tau_{\varepsilon} \omega, x, e^{-\Lambda t} u_{\varepsilon}(t)) - \frac{\Lambda}{2} r(\tau_{\varepsilon} \omega, x) |u_{\varepsilon}(t)|^2 dx \right\rangle \\ & \geq \left\langle \int_Q e^{2\Lambda t} f(\omega, x, e^{-\Lambda t} u(t)) - \frac{\Lambda}{2} r(\omega, x) |u(t)|^2 dx \right\rangle. \end{aligned}$$

Using the above two statements we conclude that

$$\liminf_{\varepsilon \rightarrow 0} \int_0^T \tilde{\mathcal{E}}_{\varepsilon}(t, u_{\varepsilon}(t)) dt \geq \int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, u(t)) dt. \quad (32)$$

In order to complete the limit passage, it is left to treat the third term on the left-hand side of (29). Using Lemma 4.4, we find $w \in L^p(0, T; L^p_{\text{inv}}(\Omega) \otimes W_0^{1,p}(Q)) \cap L^{\theta}(0, T; L^{\theta}_{\text{inv}}(\Omega) \otimes L^{\theta}(Q))$ such that

$$\int_0^T \tilde{\mathcal{E}}_{\text{hom}}^*(t, -D\mathcal{R}_{\text{hom}}(\dot{u}(t))) dt = \int_0^T \langle -D\mathcal{R}_{\text{hom}}(\dot{u}(t)), w(t) \rangle_{Y_0^*, Y_0} - \tilde{\mathcal{E}}_{\text{hom}}(t, w(t)) dt. \quad (33)$$

Moreover, by the second claim of Lemma 4.4, we find $\chi \in L^p(0, T; L^p_{\text{pot}}(\Omega) \otimes L^p(Q))$ such that

$$\begin{aligned} \int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, w(t)) dt &= \int_0^T e^{2\Lambda t} \left\langle \int_Q V(\omega, x, e^{-\Lambda t} \nabla w(t) + \chi(t)) + f(\omega, x, e^{-\Lambda t} w(t)) \right\rangle \\ &\quad - \Lambda \mathcal{R}_{\text{hom}}(w(t)) dt. \end{aligned} \quad (34)$$

For the pair $(w, e^{\Lambda \cdot} \chi(\cdot))$ ($e^{\Lambda \cdot}$ denotes the function $t \mapsto e^{\Lambda t}$) Lemma 4.3 implies the existence of $w_{\varepsilon} \in L^p(0, T; L^p(\Omega) \otimes W_0^{1,p}(Q)) \cap L^{\theta}(0, T; L^{\theta}(\Omega \times Q))$ such that

$$\begin{aligned} \mathcal{T}_{\varepsilon} w_{\varepsilon} &\rightarrow w \quad \text{strongly in } L^{\theta}(0, T; L^{\theta}(\Omega \times Q)), \\ \mathcal{T}_{\varepsilon} \nabla w_{\varepsilon} &\rightarrow \nabla w + e^{\Lambda \cdot} \chi \quad \text{strongly in } L^p(0, T; L^p(\Omega \times Q)^d). \end{aligned} \quad (35)$$

Using the definition of the convex conjugate $\tilde{\mathcal{E}}_{\varepsilon}^*$, we have

$$\int_0^T \tilde{\mathcal{E}}_{\varepsilon}^*(t, -D\mathcal{R}_{\varepsilon}(\dot{u}_{\varepsilon}(t))) dt \geq \int_0^T \langle -D\mathcal{R}_{\varepsilon}(\dot{u}_{\varepsilon}(t)), w_{\varepsilon}(t) \rangle_{Y^*, Y} - \tilde{\mathcal{E}}_{\varepsilon}(t, w_{\varepsilon}(t)) dt.$$

For the first term on the right-hand side we have, using the fact that the extended unfolding operator is unitary, as $\varepsilon \rightarrow 0$,

$$\begin{aligned} \int_0^T \langle -D\mathcal{R}_\varepsilon(\dot{u}_\varepsilon(t)), w_\varepsilon(t) \rangle_{Y^*, Y} dt &= - \int_0^T \left\langle \int_Q r(\omega, x) \mathcal{T}_\varepsilon \dot{u}_\varepsilon(t) \mathcal{T}_\varepsilon w_\varepsilon(t) dx \right\rangle dt \quad (36) \\ &\rightarrow - \int_0^T \left\langle \int_Q r(\omega, x) \dot{u}(t) w(t) dx \right\rangle dt = \int_0^T \langle -D\mathcal{R}_{\text{hom}}(\dot{u}(t)), w(t) \rangle_{Y_0^*, Y_0} dt. \end{aligned}$$

The above convergence follows since (36) is a scalar product of a strongly and a weakly convergent sequence. Moreover, by Proposition 3.5 (i),

$$\begin{aligned} &\int_0^T \tilde{\mathcal{E}}_\varepsilon(t, w_\varepsilon(t)) dt \\ &= \int_0^T e^{2\Lambda t} \left\langle \int_Q V(\omega, x, e^{-\Lambda t} \mathcal{T}_\varepsilon \nabla w_\varepsilon(t)) + f(\omega, x, e^{-\Lambda t} \mathcal{T}_\varepsilon w_\varepsilon(t)) dx \right\rangle dt \\ &\quad - \int_0^T \left\langle \int_Q \frac{\Lambda r}{2} |\mathcal{T}_\varepsilon w_\varepsilon(t)|^2 dx \right\rangle dt. \end{aligned}$$

As $\varepsilon \rightarrow 0$, this expression converges to

$$\int_0^T e^{2\Lambda t} \left\langle \int_Q V(\omega, x, e^{-\Lambda t} \nabla w(t) + \chi(t)) + f(\omega, x, e^{-\Lambda t} w(t)) - \frac{\Lambda r}{2e^{2\Lambda t}} |w(t)|^2 dx \right\rangle dt.$$

This follows completely analogously to the proof of Proposition 3.5 (ii) using the strong convergences (35) and the growth conditions of the integrands (standard argument using the dominated convergence theorem). By (34), the last expression equals $\int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, w(t)) dt$ and therefore collecting the above statements we conclude that

$$\liminf_{\varepsilon \rightarrow 0} \int_0^T \tilde{\mathcal{E}}_\varepsilon^*(t, -D\mathcal{R}_\varepsilon(\dot{u}_\varepsilon(t))) dt \geq \int_0^T \tilde{\mathcal{E}}_{\text{hom}}^*(t, -D\mathcal{R}_{\text{hom}}(\dot{u}(t))) dt, \quad (37)$$

where we also use (33).

Collecting (30), (31), (32) and (37), we obtain that

$$\begin{aligned} &\int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, u(t)) + \tilde{\mathcal{E}}_{\text{hom}}^*(t, -D\mathcal{R}_{\text{hom}}(\dot{u}(t))) dt \\ &\leq -\mathcal{R}_{\text{hom}}(u(T)) + \mathcal{R}_{\text{hom}}(u(0)) = \int_0^T \langle -D\mathcal{R}_{\text{hom}}(\dot{u}(t)), u(t) \rangle_{Y_0^*, Y_0} dt. \end{aligned}$$

This inequality is, in fact, an equality by the Fenchel-Young inequality. Since $u(t) = e^{\Lambda t} y(t)$, Lemma 4.1 (iii) implies that y is the unique solution to (11) with $y(0) = y^0$. Furthermore, using (30) and (31) we obtain

$$\limsup_{\varepsilon \rightarrow 0} (-\mathcal{R}_\varepsilon(u_\varepsilon(T)) + \mathcal{R}_\varepsilon(u_\varepsilon(0))) \leq -\mathcal{R}_{\text{hom}}(u(T)) + \mathcal{R}_{\text{hom}}(u(0)).$$

Also, exploiting the equality (29) and the liminf inequalities (32), (37), we obtain

$$\begin{aligned} \liminf_{\varepsilon \rightarrow 0} (-\mathcal{R}_\varepsilon(u_\varepsilon(T)) + \mathcal{R}_\varepsilon(u_\varepsilon(0))) &\geq \int_0^T \tilde{\mathcal{E}}_{\text{hom}}(t, u(t)) + \tilde{\mathcal{E}}_{\text{hom}}^*(t, -D\mathcal{R}_{\text{hom}}(\dot{u}(t))) dt \\ &= -\mathcal{R}_{\text{hom}}(u(T)) + \mathcal{R}_{\text{hom}}(u(0)). \end{aligned}$$

This results in

$$\lim_{\varepsilon \rightarrow 0} \frac{e^{2\Lambda T}}{2} \left\langle \int_Q r(\omega, x) |\mathcal{T}_\varepsilon y_\varepsilon(T)|^2 dx \right\rangle = \lim_{\varepsilon \rightarrow 0} \mathcal{R}_\varepsilon(u_\varepsilon(T)) = \mathcal{R}_{\text{hom}}(u(T)),$$

where we use that $\mathcal{R}_\varepsilon(u_\varepsilon(0))$ converges to $\mathcal{R}_{\text{hom}}(u(0))$. Noting that $\mathcal{R}_{\text{hom}}(u(T)) = \frac{\varepsilon^{2\Lambda T}}{2} \left\langle \int_Q r(\omega, x) |y(T)|^2 dx \right\rangle$, the above and (26) imply that $\mathcal{T}_\varepsilon y_\varepsilon(T) \rightarrow y(T)$ strongly in Y . Since $\mathcal{T}_\varepsilon y(T) = y(T)$ by shift-invariance of $y(T)$, we obtain that $y_\varepsilon(T) \rightarrow y(T)$ strongly in Y . We may replace T by any $t \in (0, T]$ in the above procedure to obtain $y_\varepsilon(t) \rightarrow y(t)$ strongly in Y . Convergence for the entire sequence is obtained by a standard contradiction argument using the uniqueness of the solution for the limit problem.

Step 4. Convergence of \dot{y}_ε and $\mathcal{E}_\varepsilon(y_\varepsilon(t))$. The EVI (7) is equivalent to the differential inclusion (cf. (1) in the Introduction)

$$0 \in D\mathcal{R}_\varepsilon(\dot{y}_\varepsilon(t)) + \partial_F \mathcal{E}_\varepsilon(y_\varepsilon(t)) \quad \text{for a.e. } t \in (0, T).$$

This and the chain rule for the Λ -convex functional \mathcal{E}_ε (see, e.g., [42]) imply that $\frac{d}{dt} \mathcal{E}_\varepsilon(y_\varepsilon(t)) = - \langle D\mathcal{R}_\varepsilon(\dot{y}_\varepsilon(t)), \dot{y}_\varepsilon(t) \rangle_{Y^*, Y}$. An integration over $(0, t)$, for an arbitrary $t \in (0, T]$, yields

$$\int_0^t \langle D\mathcal{R}_\varepsilon(\dot{y}_\varepsilon(s)), \dot{y}_\varepsilon(s) \rangle_{Y^*, Y} ds = \mathcal{E}_\varepsilon(y_\varepsilon(0)) - \mathcal{E}_\varepsilon(y_\varepsilon(t)).$$

Since $y_\varepsilon(t) \rightarrow y(t)$ strongly in Y and $y(t)$ is shift-invariant, it follows that $\mathcal{T}_\varepsilon y_\varepsilon(t) \rightarrow y(t)$ strongly in Y . As a result of this and using the weak convergence in (27), similarly to the proof of (32), we obtain that $\liminf_{\varepsilon \rightarrow 0} \mathcal{E}_\varepsilon(y_\varepsilon(t)) \geq \mathcal{E}_{\text{hom}}(y(t))$ (by employing Proposition 3.5). As a consequence, using the additional assumption $\mathcal{E}_\varepsilon(y_\varepsilon(0)) \rightarrow \mathcal{E}_{\text{hom}}(y(0))$, we obtain

$$\begin{aligned} \limsup_{\varepsilon \rightarrow 0} \int_0^t \langle D\mathcal{R}_\varepsilon(\dot{y}_\varepsilon(s)), \dot{y}_\varepsilon(s) \rangle_{Y^*, Y} ds &\leq \mathcal{E}_{\text{hom}}(y(0)) - \mathcal{E}_{\text{hom}}(y(t)) \\ &= \int_0^t \langle D\mathcal{R}_{\text{hom}}(\dot{y}(s)), \dot{y}(s) \rangle_{Y_0^*, Y_0} ds, \end{aligned}$$

where in the last equality we use that y is the solution to the limit problem. Note that it holds $\int_0^t \langle D\mathcal{R}_\varepsilon(\dot{y}_\varepsilon(s)), \dot{y}_\varepsilon(s) \rangle_{Y^*, Y} ds = \int_0^t \left\langle \int_Q r |\mathcal{T}_\varepsilon \dot{y}_\varepsilon(s)|^2 dx \right\rangle ds$ and since $\mathcal{T}_\varepsilon \dot{y}_\varepsilon \rightharpoonup \dot{y}$ weakly in $L^2(0, T; Y)$, it follows that

$$\liminf_{\varepsilon \rightarrow 0} \int_0^t \langle D\mathcal{R}_\varepsilon(\dot{y}_\varepsilon(s)), \dot{y}_\varepsilon(s) \rangle_{Y^*, Y} ds \geq \int_0^t \langle D\mathcal{R}_{\text{hom}}(\dot{y}(s)), \dot{y}(s) \rangle_{Y_0^*, Y_0} ds.$$

Combining the last two inequalities and the weak convergence $\mathcal{T}_\varepsilon \dot{y}_\varepsilon \rightharpoonup \dot{y}$, we conclude that for all $t \in (0, T]$,

$$\dot{y}_\varepsilon \rightarrow \dot{y} \quad \text{strongly in } L^2(0, t; Y), \quad \mathcal{E}_\varepsilon(y_\varepsilon(t)) \rightarrow \mathcal{E}_{\text{hom}}(y(t)).$$

□

Appendix A. Normal integrands and integral functionals. In the following we recall some key facts about measurable integrands and conjugates of integral functionals. A detailed and more general theory can be found in [41].

Let (S, Σ, μ) be a complete measure space with a σ -finite measure μ and let X be a separable reflexive Banach space with dual space X^* . The product- σ -algebra of Σ and $\mathcal{B}(X)$ (Borel σ -algebra on X) is denoted by $\Sigma \otimes \mathcal{B}(X)$. In the following we refer to a function $f : S \times X \rightarrow \mathbb{R} \cup \{\infty\}$ as an *integrand*. For $s \in S$, we denote the function $x \mapsto f(s, x)$ by f_s .

Definition A.1 (Normal integrand). We say that an integrand f is *normal* if the following two conditions hold:

- (i) f is $\Sigma \otimes \mathcal{B}(X)$ -measurable.
- (ii) For each $s \in S$, the function f_s is proper and l.s.c.

If additionally, for each $s \in S$, f_s is convex, we say that f is a *convex normal integrand*.

Note that if f is a normal integrand and $x : S \rightarrow X$ is a $(\Sigma, \mathcal{B}(X))$ -measurable function, then $s \mapsto f(s, x(s))$ defines a Σ -measurable mapping.

Remark A.2 (Carathéodory integrand). We call an integrand f *Carathéodory* if f is finite everywhere, $f(\cdot, x)$ is Σ -measurable for all $x \in X$, and $f(s, \cdot)$ is continuous for all $s \in S$. If an integrand is Carathéodory, then it is normal (for the proof see, e.g., [1, Lemma 4.51]).

Let f be a normal integrand. We define $f^* : S \times X^* \rightarrow \mathbb{R} \cup \{\infty\}$ to be the convex conjugate of f in its second variable, i.e., $f^*(s, \xi) = f_s^*(\xi)$ is defined by

$$f_s^*(\xi) = \sup_{x \in X} \left(\langle \xi, x \rangle_{X^*, X} - f_s(x) \right).$$

Proposition A.3 ([41, Proposition 2]). *Let f be a normal integrand. If for each $s \in S$, f_s^* is proper (this is true if, e.g., $f \geq -c$ for some $c > 0$), then f^* is a convex normal integrand. If f is a convex normal integrand, then $(f^*)^* = f$.*

Let $p \in (1, \infty)$ and $q = \frac{p}{p-1}$ be its dual exponent of integrability. Since μ is σ -finite, we may identify $L^p(S; X)^*$ with $L^q(S; X^*)$ (see [47, Theorem 1.5]). For a given normal integrand f , we define an integral functional $I_f : L^p(S; X) \rightarrow \mathbb{R} \cup \{\infty\}$ by

$$I_f(x) = \int_S f(s, x(s)) d\mu(s),$$

if $s \mapsto f(s, x(s))$ defines an element in $L^1(S)$ and otherwise we set I_f to be $+\infty$. Analogously, we define $I_{f^*} : L^q(S; X^*) \rightarrow \mathbb{R} \cup \{\infty\}$.

Proposition A.4 ([41, Theorem 2]). *Let $p \in (1, \infty)$, $q = \frac{p}{p-1}$. Let f be a normal integrand. If there is an element $x \in L^p(S; X)$ such that $I_f(x) < \infty$, then for all $\xi \in L^q(S; X^*)$, it holds*

$$I_{f^*}(\xi) = \sup_{x \in L^p(S; X)} \left(\int_S \langle \xi(s), x(s) \rangle_{X^*, X} d\mu(s) - I_f(x) \right). \quad (38)$$

Remark A.5 (Measurable selection). The above theorem implies a measurable selection principle for parametrized minimization problems. Namely, setting $\xi = 0$ above, we have

$$\int_S \inf_{x \in X} f(s, x) d\mu(s) = \inf_{x \in L^p(S; X)} \int_S f(s, x(s)) d\mu(s).$$

In particular, if the minimum on the right-hand side is attained, the latter equality implies that there exists a $(\Sigma, \mathcal{B}(X))$ -measurable function $x : S \rightarrow X$ such that $\inf_{x \in X} f(s, x) = f(s, x(s))$ μ -a.e.

Acknowledgments. The authors thank Alexander Mielke and Goro Akagi for useful discussions and valuable comments. MH has been funded by Deutsche Forschungsgemeinschaft (DFG) through grant CRC 1114 “Scaling Cascades in Complex Systems”, Project C05 “Effective models for materials and interfaces with many scales”. SN and MV acknowledge funding by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) – project number 405009441, and in the context of TU Dresden’s Institutional Strategy “*The Synergetic University*”.
